Abstract

The diffusion of automation technology raises questions about the future of work, leading to calls for policy interventions. The ongoing debate centers on the decisions made by technology adopters. In this paper, I study supply-side adjustments and their role in shaping policy outcomes. I focus on the global market for industrial robots, a leading type of automation technology, where a few multinational enterprises (MNEs) dominate sales. To evaluate how these MNEs respond to policy changes, I collect new data on their characteristics and global sales networks. I then develop and estimate a multi-country general equilibrium model featuring oligopolistic multinational robot sellers. Using this model, I find that MNEs' market entry and pricing responses transmit internationally and amplify the aggregate and distributional effects of policies targeting robots.

1 Introduction

The diffusion of automation technologies, including robotics and artificial intelligence, raises questions about the future of work. On the one hand, these technologies autonomously perform several complex tasks, fostering productivity growth. On the other, their adoption raises concerns about job displacement and inequality. For these reasons, academics and policymakers discuss policies to regulate automation (Brynjolfsson and McAfee, 2014; Acemoglu and Johnson, 2023).

Current discussions focus on how policy interventions affect the production and employment decisions of technology adopters (Guerreiro et al., 2022; Thuemmel, 2022; Beraja and Zorzi, 2025). However, since automation technology supply is often dominated by a few large multinational enterprises (MNEs) active in multiple countries, responses from the supply side may be sizable and represent a determining factor for the ultimate effects of any policy. Studying the supply of automation technologies is challenging, as there is limited evidence on automation suppliers and their activities in the global economy. Additionally, a theoretical framework that accounts for the features of the global automation industry is necessary to disentangle adjustments in supply and demand after a policy change.

In this paper, I offer three contributions. First, I compile novel data and document new facts about the global market for industrial robots (henceforth “robots”).¹ This market is ideal for studying automation supply, as four MNEs account for over 50% of global sales (Leigh and Kraft, 2018), and robots are a leading type of automation technology (Acemoglu and Restrepo, 2020). Second, I develop a quantitative multi-country general equilibrium model with oligopolistic multinational robot sellers and heterogeneous households, who can be either complements or substitutes to robots in final goods production. The model delivers predictions about how competition within the robot industry shapes prices, wages, output, and welfare in each market. Third, I use the model to evaluate how policy interventions targeting robot adoption shape these outcomes in the global economy, focusing on the role of supply-side responses. I show that ignoring MNEs’ market entry and pricing responses leads to an underestimation of the aggregate and distributional outcomes of policies aimed at protecting workers displaced by robots by about 20%. Moreover, policies that boost competition among robot sellers raise output but also increase inequality due to robots’ non-neutrality.

¹Industrial robots are defined by the International Organization for Standardization (ISO) as “automatically controlled, reprogrammable multipurpose manipulators”. See Section 2 for more details.

I begin by describing the three main stages around which the global robot industry is organized: production, integration, and adoption. Over half of the world’s robots are produced in Japan and Germany, where most MNEs are headquartered. Along with China, South Korea, and the US, these countries are also the top destinations for robot adoption. The integration stage is key. Robot sales entail a bundle of generic robots and “integration services”, such as customization, setup, and maintenance, to adapt pre-built machines to specific production tasks. To deliver these services, robot sellers establish local retail networks in each market they serve.

I collect data from multiple sources for each stage of the chain. I identify the MNEs that produce and sell robots from the list of members of the International Federation of Robotics (IFR). Information about the location of their headquarters (HQ), financial accounts, and ownership structure comes from the Moody’s Orbis dataset. By scraping the website of each MNE, I also geolocate their branches that sell generic robots and integration services to users worldwide. I retrieve over 600 sales branches in total. About 90% of them are in Orbis. Countries’ characteristics, such as the number of robots adopted, market size, and trade flows and barriers, come from commonly used data sources. The final dataset is a cross-section of 10 multinational robot sellers and 45 countries, pooling information between 2019 and 2021. These 10 MNEs account for about 90% of global robot sales. The 45 countries I consider account for more than 90% of world GDP.

Using these data, I document two new facts. First, robot sales decrease as the distance between destination countries and the robot sellers’ HQ increases. This fact suggests that multinational robot sellers face bilateral frictions that increase with distance from their HQ, which is consistent with gravity. Second, robot sales in destination countries are highly concentrated, with only half of all robot sellers serving the average country in the data. This fact is consistent with robot sellers having market power.

These facts inform, and are replicated by, a multi-country general equilibrium model featuring multinational robot sellers and heterogeneous households. To capture oligopolistic competition among robot sellers, I build upon state-of-the-art frameworks developed for analyzing oligopoly in general equilibrium ([Atkeson and Burstein, 2008](#); [Gaubert and Itskhoki, 2021](#)), adapting them to the specific features of the global robot industry. Household behavior and their interaction with robots in production are standard and based on the canonical framework of [Acemoglu and Restrepo \(2018\)](#). I use the model to assess how multinational robot sellers respond to policy interventions and

how their responses influence equilibrium outcomes worldwide.

The model setup is as follows. Each market consists of households and perfectly competitive final goods producers. Households buy final goods and supply either routine or non-routine labor inelastically. Firms use robots and both types of labor to produce final goods. As standard in the automation literature, robots are substitutes to routine workers and complements to non-routine ones. Final goods are traded internationally subject to iceberg trade costs, creating linkages across markets.

Robot supply has two key features. First, upon paying an entry cost, robot sellers can serve multiple markets. Second, within each market, they compete to sell an indivisible bundle of generic robots and integration services to users. This bundle, which I refer to as a “product”, is considered non-tradable and produced in destination markets using non-routine local labor.² Robot sellers are heterogeneous in terms of appeal to final goods producers, which is captured by a seller-market-specific demand shifter. More appealing robot sellers enter more markets and charge higher markups.

Bringing the model to the data requires determining the structural parameters of the model. The households’ and final goods producers’ parameters are standard and can be calibrated from the data or existing literature. The robot sellers’ parameters are new, and I estimate them using a simulated method of moments (SMM) procedure. The SMM estimator targets moments informative about robot sellers’ entry choices and sales, market competition, and robot adoption. It recovers the mean and standard deviation of the appeal distribution across robot sellers, the cost of entering markets, and the elasticity of substitution between the different products offered by robot sellers. While jointly estimated, each parameter is intuitively informed by specific targeted moments, which are accurately replicated. I validate the model by showing that it matches untargeted seller and market-level moments.

I use the model to evaluate two counterfactual policy interventions. The first focuses on protecting workers more exposed to automation. The second seeks to increase the efficiency of the robot industry by promoting competition among robot sellers.

For the first set of policies, I examine the effects of a European-wide value-added robot tax paid by robot adopters. This policy was discussed by the European Parliament in 2017 as part of a law aimed at protecting workers exposed to automation, and

²This assumption allows me to abstract from the proximity-concentration trade-off in the production of generic robots and analyze competition in destination markets. It is supported by the fact that locally provided integration services account for about two-thirds of the final price paid by robot users (Leigh and Kraft, 2018).

it has prompted research on the taxation of automation technology (Guerreiro et al., 2022; Thuemmel, 2022; Costinot and Werning, 2023).³ I consider a 5% tax, in line with the short-run optimal robot tax rate estimated for the US by Guerreiro et al. (2022). I explore two scenarios. In the first, in line with the existing literature, robot sellers cannot adjust market entry choices and markups after the tax is introduced. In the second, they can adjust along both margins. Without supply-side responses, a tax reduces robot demand and increases the price of final goods, generating an output loss in the EU. However, losses are not evenly borne. Routine workers experience an increase in welfare because of their substitutability with robots, while non-routine workers face a welfare loss due to their complementarity.

In the second scenario, a tax shrinks the total size of the market, and some robot sellers leave the EU. Exit induces a reallocation of market shares to incumbents, who raise their markups, leading to a stronger increase in the price of robots and a larger output loss than in the first case. Routine workers experience smaller welfare gains, while non-routine workers face stronger losses. Overall, supply-side responses amplify the aggregate and distributional effects of a tax on robot adoption by about 20%.

By increasing the price of EU goods, an EU-wide robot tax also increases consumer prices and reduces the welfare of all households outside the EU. In this case as well, ignoring the endogenous market entry and prices responses of multinational robot sellers leads to underestimating the welfare losses beyond the EU. Interestingly, because of gravity in robot sales, an EU-wide tax disproportionately affects robot sellers headquartered outside the EU, who experience higher exit rates, effectively making the tax a protectionist measure from the perspective of the EU.

For the second set of policies, I consider interventions that address inefficiencies arising from robot sellers' market power by favoring entry into robot production and sales. Counterfactual results show that boosting competition among robot sellers reduces markups and prices, increasing robot adoption and final output. If entry generates sufficiently strong pro-competitive effects, all types of workers can be made better off. However, the non-neutrality of robots implies that non-routine workers experience disproportionately larger gains. Therefore, a planner that seeks to maximize efficiency but also protect workers displaced by robots should promote competition among multinational robot sellers and reallocate income towards routine workers.

³Guerreiro et al. (2022) show that when lump-sum transfers are unfeasible (e.g., because the planner does not observe the worker type, as in Mirrlees, 1971), it is optimal to tax robot adoption to redistribute income towards routine workers.

Related Literature. This paper contributes to the literature on quantitative models of MNEs’ activities (e.g., [Irrazabal et al., 2013](#); [Ramondo and Rodríguez-Clare, 2013](#); [Ramondo, 2014](#); [Tintelnot, 2017](#); [Antràs et al., 2017](#); [Arkolakis et al., 2018](#); [Alviarez, 2019](#); [Head and Mayer, 2019](#); [Arkolakis et al., 2023](#)). From a theoretical perspective, it offers two contributions. First, instead of focusing on horizontal, vertical, or export-platform foreign direct investment (FDI), this paper provides a model of distribution FDI tailored to the robot industry. Second, it relaxes the conventional assumption of monopolistic competition among MNEs, allowing for oligopolistic competition. From an empirical standpoint, this work introduces new data on MNEs in the robot industry.

This paper also contributes to the literature on oligopoly in international trade (e.g., [Markusen, 1981](#); [Brander and Krugman, 1983](#); [Brander and Spencer, 1985](#); [Atkeson and Burstein, 2008](#); [Edmond et al., 2015](#); [Neary, 2016](#); [Parenti, 2018](#); [Gaubert and Itskhoki, 2021](#); [Impullitti et al., 2022](#); [Crowley et al., 2024](#)). The existing literature focuses on how imperfect competition between firms shapes international trade and influences trade policy. This paper shows how firms’ strategic behaviors influence the outcomes of interventions beyond trade policy.

By describing how a few firms dominate the global robot industry, this paper connects with the literature on global market power (e.g., [De Loecker and Eeckhout, 2018](#); [De Loecker et al., 2020](#); [Alviarez et al., 2020](#); [Autor et al., 2020](#); [Leone et al., 2024](#)). Properly adapted, the model developed in this paper can be used to assess the role of market power in transmitting shocks in other globally concentrated input markets.

Finally, this paper contributes to the literature on the effects of automation technology (e.g., [Acemoglu and Restrepo, 2018](#); [Graetz and Michaels, 2018](#); [Bessen et al., 2019](#); [Acemoglu and Restrepo, 2020](#); [Acemoglu et al., 2020](#); [Koch et al., 2021](#); [Aghion et al., 2020](#); [Dauth et al., 2021](#); [Hubmer and Restrepo, 2021](#); [Hémous and Olsen, 2022](#); [Acemoglu et al., 2023](#); [Giuntella et al., 2024](#)) and the implications of policies targeting automation (e.g., [Humlum, 2021](#); [Guerreiro et al., 2022](#); [Thuemmel, 2022](#); [Costinot and Werning, 2023](#); [Beraja and Zorzi, 2025](#)). The main contribution is highlighting the role of the supply side in shaping the outcomes of policies favoring or constraining automation technology.

The paper unfolds as follows. Section 2 provides information about the robot industry. Section 3 introduces the data. Section 4 describes the empirical facts. Section 5 contains the model. Section 6 discusses estimation and fit. Sections 7 and 8 analyze the effects of a robot tax and competition policy, respectively. Section 9 concludes.

2 Industry Background

This section provides background information about robots and the robot industry.

2.1 Industrial Robots

Industrial robots (henceforth robots) are defined by the International Organization for Standardization (ISO) as “automatically controlled, reprogrammable multipurpose manipulators, programmable in three or more axes, which can be either fixed in place or mobile for use in industrial automation applications” (ISO 8372:2012). The ability to perform different tasks without any human supervision is the main feature of these machines ([International Federation of Robotics, 2020](#)). Using data between 1990 and 2007 on US labor markets, [Acemoglu and Restrepo \(2020\)](#) document that autonomy makes robots more substitutable for workers in routine occupations compared to computers and other automation technology. Overall, robots contribute to about 10% of the total market value of the automation industry ([UBS, 2020](#)).

At the factory gate, robots are classified as relatively homogenous goods. There is a single six-digit HS code associated with robots, and the same holds true in the US ten-digit HTS product classification, the most disaggregated one in international trade data.⁴ For comparison, another product for which these classifications coincide is white portland cement. As explained below, robot sellers provide “integration services” to end users to tailor generic robots to their specific production needs.

2.2 The Global Robot Industry

The global robot industry is organized along three main stages: production, integration, and adoption. Japan assembles nearly half of the world’s new robots each year. Other major production centers are China, Germany, Italy, South Korea, and the US ([International Federation of Robotics, 2020](#)). More details regarding the locations where robots are produced and the technological requirements of the production process are in Online Appendices [C.1](#) and [C.2](#), respectively.

In the early 1990s, industrial robots were mostly employed in the automotive industry. However, over the last 30 years, their adoption has grown across other manufac-

⁴Robots belong to six different types (articulated, cartesian, cylindrical, spherical, parallel, and SCARA—Selective Compliance Assembly Robot Arm) mainly differing in terms of number of arms and payload. All types fall within the HS6 code 847950.

turing sectors, such as chemicals, electronics, pharmaceuticals, and even agriculture. Overall, their global stock has increased fivefold. China, Germany, Japan, South Korea, and the US are the major destination markets for robots ([International Federation of Robotics, 2020](#)). Robot adopters tend to be large manufacturing companies ([Acemoglu et al., 2020](#)), often belonging to multinational groups ([Leone, 2024](#)).

The integration stage is a key feature of the industry. Robots are sophisticated machines, and their adoption is associated with a broader restructuring of production ([Koch et al., 2021](#)). Therefore, robot sales entail a bundle of generic robot arms and integration services. These services involve guidance in selecting the appropriate automation solution, product customization to adapt a generic robot to a specific production task, and post-sale support like installation, replacement, and ongoing maintenance. Online Appendix C.3 provides examples based on case studies available from the robot sellers’ websites. [Leigh and Kraft \(2018\)](#) estimate that integration services account for about two-thirds of the final price paid by users.

The bundling of robots and integration services is crucial. While generic robots are tradable, integration services require proximity to final demand. Therefore, sellers must establish a retail network of branches in each market they serve, regardless of where production facilities are located.

3 Data

This section presents new data about robot sales and the additional data sources.

3.1 Multinational Robot Sellers

Identity. I obtain a list of robot sellers using the directory of members of the International Federation of Robotics (IFR). The original directory contains 85 members. Among them, there are 26 firms that produce and sell robots. The remaining members are either national associations or research institutes. To identify industry leaders, I resort to business-related sources and the Moody’s Orbis dataset, proceeding in two steps. First, I search for these 26 firms in magazines discussing trends in the industrial robot sector. Second, I select the companies that consistently emerge as industry leaders across searches. The final list includes ABB, Comau, Epson, Fanuc, Kawasaki, Kuka, Nachi-Fujikoshi, Omron, Staubli, and Yaskawa. Using Orbis, I verify that these

10 sellers account for approximately 90% of the global market share.⁵ Among them, ABB, Fanuc, Kuka, and Yaskawa alone hold approximately 54% of the global market share, as shown in Online Figure A.1. These concentration patterns align with existing industry reports (UBS, 2020).⁶

Characteristics. I gather several characteristics of robot sellers from Orbis, including information about their sectors of activity, sales, employment, fixed assets, and R&D expenses. I also collect information about the location of robot sellers’ headquarters (HQ), their corporate structure, and the activities of their subsidiaries, even those unrelated to robots. All firms are MNEs with subsidiaries in multiple countries. Using Orbis Intellectual Property, I also collect information about robot-related patents. Among the 26 sellers registered with the IFR, the top 10 accounting for 90% of global sales also hold 81% of the global stock of robot-related patents. See Online Appendix C.2 for more details.

Global Sales Network. Section 2.2 emphasizes that robot sellers need a retail network in each market to provide integration services to their customers. Unfortunately, information about retail networks cannot always be obtained from Orbis for two reasons. First, Orbis only links branches to sellers if they share a common owner (usually the multinational seller itself). However, business-related case studies available on the robot sellers’ websites suggest that some branches may also function as franchises. Second, even among affiliates, branches that supply robots and integration services cannot be unambiguously identified when information about their sector of activity is missing from Orbis.

To address this limitation, I create a web scraping algorithm to retrieve information about branches supplying robots and integration services directly from the websites of the top 10 robot sellers. The algorithm works in two steps. First, it navigates to the “Where to find us” section of each seller’s website, where a list of retail branches

⁵This share refers to 2021 but it is stable over time. Because Orbis does not report turnover by sector, I compute global market shares using sellers’ total turnover. Since automation provision is the primary activity of these firms, their total sales are an accurate proxy for their size in the industry. This is not the case for other automation sectors. For example, Amazon and Microsoft dominate cloud computing services, but their total sales in Orbis likely reflect income from their other main activities. This makes the robot industry appealing to study market structure in the automation sector.

⁶For reference, Online Figure A.2 shows that firms in the robot industry are relatively small compared to leading companies in other sectors, such as cars, smartphones, semiconductors, and computers.

across the world is provided. Second, it extracts and stores the name and geographical location of each branch. Online Figure A.3 illustrates two examples of the online information retrieved. The first branch is a subsidiary of Kuka, while the second is a franchise selling ABB robots. Online Appendix D.1 provides additional information about the algorithm.

Using this procedure, I identify 603 sales branches located in multiple countries, which are shown in Online Figure A.4. Among all branches, 538 (89%) can be found in Orbis, and I collect information about their accounts and corporate structure. Ownership details are available for 409 (75%) branches. Approximately 65% of them are subsidiaries. The remaining 35% are franchises. However, since each franchise is only listed on a single robot seller’s website, I do not distinguish between branches owned by sellers and those operating at arm’s length.

Market Shares. I measure the market share of a seller in each market using its share of branches in that market. This choice is motivated by the importance of physical proximity to end-users for sales, and rests on the assumption that robot sellers with more local branches have higher sales. In Online Appendix D.2, I provide evidence in support of this assumption using Orbis information about branch-level sales data.⁷ I prefer the definition of market shares based on branches over the one based on sales because the latter cannot always be defined due to missing information in Orbis. I defer a formal treatment of the relevant markets in which robot sellers compete until Section 6.

3.2 Additional Data Sources

Robot Adoption. Data about robot adoption come from the IFR, which aggregates cross-country firm-level information and computes the number of robots used in every country by industry (roughly matching the NACE4 classification) and year. These data are considered as very reliable and have been extensively used in previous research (Graetz and Michaels, 2018; Acemoglu and Restrepo, 2020; Dauth et al., 2021).

International Trade. Information about bilateral trade flows between countries by industry (ISIC Review 4) is obtained from the World Input-Output Tables (WIOT).

⁷In Online Appendix E.1, I extend the model in Section 5 to provide a micro-foundation for the positive correlation between robot sellers’ number of branches and sales in a market.

Bilateral trade flows by specific goods (HS6 classification) come from the CEPII BACI dataset. These data also report the value and quantity of trade in robots.

To complement the trade data, I collect bilateral information about physical and cultural distance between countries. Physical distance, measured as the distance between the two most populated cities of a country pair in kilometers, comes from the CEPII gravity database. Cultural distance, measured as the probability that two random individuals in two countries speak the same language, comes from [Gurevich et al. \(2021\)](#). I obtain information on bilateral trade costs, computed using the method developed by [Novy \(2013\)](#), from the ESCAP-World Bank Trade Cost Database.

Country Characteristics. Information about the characteristics of the countries served by robot sellers come from various sources. From the World Development Indicators (WDI) database of the World Bank, I collect information about GDP (in 2010 USD PPP), total population, employment, value added by industry, and land area. The geographical coordinates of each country come from the CEPII gravity database.

3.3 Final Sample

Summary Statistics. The matched dataset is a cross-section of 10 multinational robot sellers and 45 countries, accounting for 90% of total robot sales and global GDP. Information about sellers and their branches is relative to 2021. Information from other data sources refers to 2019, except for the WIOT database, whose latest available year is 2014.

Table 1 shows that there is substantial variation in multinational robot sellers' market entry choices and sales. For instance, Kuka and Yaskawa enter 41 and 27 countries, with an average of 2.80 and 1.44 branches per country, respectively. On the other hand, ABB and Fanuc serve fewer countries, 17 and 16 respectively, but have a higher average number of branches, 7.59 and 4.38 respectively. In general, the top 4 multinational robot sellers serve more countries and have higher market shares than the others, as shown in Online Figure A.5.

Sellers serve different countries in terms of distance from their HQ. There is also substantial dispersion in their total sales. This heterogeneity will ultimately inform the structural parameters of the model governing the decisions of robot sellers.

Table 1. SUMMARY STATISTICS

| Name | HQ | No. Countries | No. Branches | Log Dist. from HQ | Log Sales |
|-----------------|----|---------------|--------------|-------------------|-----------|
| ABB | CH | 17 | 7.59 | 8.39 | 10.36 |
| Fanuc | JP | 16 | 4.38 | 8.98 | 8.70 |
| Yaskawa | JP | 27 | 1.44 | 9.04 | 8.33 |
| Kuka | DE | 41 | 2.80 | 8.48 | 8.23 |
| Kawasaki | JP | 12 | 2.33 | 8.84 | 9.41 |
| Epson | JP | 8 | 4.00 | 9.59 | 9.13 |
| Omron | JP | 23 | 2.30 | 8.97 | 8.74 |
| Nachi-Fujikoshi | JP | 16 | 3.69 | 8.91 | 7.61 |
| Staubli | CH | 31 | 1.23 | 8.45 | 5.70 |
| Comau | IT | 23 | 1.74 | 8.35 | 5.54 |

Note: The table shows summary statistics for each of the top 10 multinational robot sellers. *HQ* is the robot sellers’ HQ country. *No. Countries* is the number of countries that robot sellers serve. *No. Branches* is the average number of branches that robot sellers operate in the countries they serve. *Log Dist. from HQ* is the log of the average distance between the two most populated cities of the robot sellers’ HQ and destination countries in kilometers. *Log Sales* is the log of robot sellers’ total revenues in million USD.

Data Validation. While the 10 robot sellers I focus on dominate the industry, there may be concerns regarding the procedure used to construct their sales network. For instance, omissions in online listings or misclassification of sales branches could introduce measurement error. To mitigate these concerns, I show that the self-collected information about global sales networks is consistent with other established sources.

First, there is a 75% correlation between the number of sales branches and robots used, as reported by the IFR, at the country level. The correlation stays unchanged even after controlling for market size. Second, there is a 77% correlation between the number of branches that sellers headquartered in country o open in country d and the export value of robots from o to d , as reported in the BACI dataset. The correlation is robust to controlling for origin and destination fixed effects, as well as the distance between country pairs. This result corroborates the argument made in Section 2.2 that robot sales are mediated by local branches, with limited scope for direct imports from producers.

Last, there is a 48% correlation between whether sellers have a branch in a country and whether they have other subsidiaries in that country (including those unrelated to robots), as reported in Orbis. The correlation is robust to controlling for seller and country fixed effects, suggesting that robot sales positively correlate with their other activities. See Online Appendix D.3 for more details about data validation.

4 Empirical Facts

This section documents novel facts about the global robot industry.

4.1 Gravity

Fact 1. *Robot sellers' entry choices and sales follow gravity.*

I estimate the following equation:

$$y_{s(o)d} = \beta \text{Log Distance from HQ}_{s(o)d} + FE_s + FE_d + \varepsilon_{s(o)d}. \quad (1)$$

$y_{s(o)d}$ is either a binary variable equal to 1 if seller s headquartered in country o has at least one branch in country d or the market share of seller s in country d (conditional on entry). $\text{Log Distance from HQ}_{s(o)d}$ is the log distance between the sellers' HQ and destination countries in kilometers. FE_s and FE_d denote seller and country fixed effects, respectively. $\varepsilon_{s(o)d}$ is the error term. Identification comes from within-seller variation after controlling for any country-level characteristics. Figure 1 shows the predicted values of equation (1) and the corresponding 95% confidence interval.

Figure 1. THE GRAVITY OF MARKET ENTRY AND MARKET SHARES

Note: The left panel plots the predicted entry probability of robot seller s in country d as a function of the log distance between the two most populated cities of the seller's HQ and destination country in kilometers. The right panel plots the predicted market share of seller s in country d as a function of the same log distance. All variables are shown after partialling out seller and country fixed effects. I standardize log distance to have zero mean and unit variance in the sample, and I plot the predicted values over its $[-1, 1]$ interval. Equation (1) is estimated via OLS. 95% heteroscedasticity-robust confidence intervals are shown.

The first column of Online Table B.1 shows that a one-standard-deviation increase in the log distance from sellers' HQ reduces the probability of entry by about 14 percentage points (28% relative to the sample average). Similarly, market shares decline by 4 percentage points (18% relative to the sample average) as shown in the second column. These findings hold when using a cultural measure of bilateral proximity, as indicated in the third and fourth columns.

Overall, there is evidence that multinational robot sellers face bilateral frictions at the extensive and intensive margins that increase with distance from their HQ, which is consistent with gravity.⁸ Several factors may underlie these frictions, including home bias in robot demand, robot sellers' limited knowledge of the needs of adopters in distant countries, or coordination costs increasing with distance from the HQ.

To replicate this fact, the model introduced in the next section allows multinational robot sellers to have different levels of appeal to robot adopters in each market they enter. This source of heterogeneity will play a crucial role in determining the sales of each robot seller in a market and how different types of robot sellers respond to policy interventions.

4.2 Granularity

Fact 2. *Robot sales in destination countries are highly concentrated.*

I estimate the following equation:

$$y_d = \alpha + \beta \text{Log Market Size}_d + \varepsilon_d. \quad (2)$$

y_d is either the total number of robot sellers active in country d or the Herfindahl–Hirschman Index (HHI) in that country.⁹ Market size of country d is approximated by its log GDP (in 2010 USD PPP). ε_d is the error term. The parameter β captures how y_d changes with market size. I standardize log GDP to have zero mean and unit variance in the sample. Therefore, α indicates the number of robot sellers or HHI in

⁸Gravity is a strong empirical regularity for trade flows (Head and Mayer, 2014) and MNEs' activities (Keller and Yeaple, 2013; Antràs and Yeaple, 2014; Gumpert, 2018). It is reassuring that well-known facts about multinational activity continue to hold in a previously unexplored sector.

⁹I define $HHI_d = \sum_{s \in S_d} s_{sd}^2$, being s_{sd} the market share of robot seller s in country d and S_d the set of robot sellers active in country d . This HHI definition implies that each country is a market in which sellers compete. Although this is reasonable for some countries, it may be inadequate for small ones belonging to the same economic or geographical areas. In Section 6, I propose a definition of markets that addresses this issue.

the average country in terms of size. Figure 2 shows the predicted values of equation (2) and the corresponding 95% confidence interval.

Figure 2. CONCENTRATION AND MARKET SIZE

Note: The left panel plots the predicted number of robot sellers in country d as a function of the log GDP of country d . The right panel plots the predicted HHI in country d as a function of the log GDP of country d . I standardize log GDP to have zero mean and unit variance in the sample, and I plot the predicted values over its $[-1, 1]$ interval. Equation (2) is estimated via OLS. 95% heteroscedasticity-robust confidence intervals are shown.

The first two columns of Online Table B.2 show that the average country hosts about 5 robot sellers, corresponding to an HHI of approximately 34%. It is useful to resort to the Horizontal Merger Guidelines of the Federal Trade Commission (FTC) to interpret these numbers. The FTC classifies markets into “unconcentrated” ($\text{HHI} < 15\%$), “moderately concentrated” ($15\% \leq \text{HHI} \leq 25\%$), and “highly concentrated” ($\text{HHI} > 25\%$). The fact that the average country falls in the third category suggests that robot sellers have market power. As expected, larger markets host more robot sellers and, therefore, are more competitive, as shown in the last two columns.

To replicate this fact, the model in the next section allows multinational robot sellers to compete oligopolistically within each local market after paying an entry cost.

5 Model

This section presents a multi-country general equilibrium model. Its main innovation is embedding competition among oligopolistic multinational robot sellers in the global economy into an established framework for studying robot adoption.

5.1 Environment

Setup. The global economy consists of \mathcal{M} markets, denoted by o (origin) or d (destination). Each market consists of households and final goods producers. Households buy final goods and supply either routine (r) or non-routine (n) labor inelastically. Final goods are produced by perfectly competitive firms using robots and both types of labor. There is international trade in final goods.

There exists a set of \mathcal{S} multinational robot sellers, each denoted by s . Robot sellers differ in terms of their appeal to final goods producers. This source of heterogeneity generates gravity in robot sales, as per Section 4.1. To account for granularity, as per Section 4.2, I let robot sellers compete oligopolistically within the robot industry.

There are two stages. In the first, after observing market entry costs, robot sellers decide which markets to serve. In the second, conditional on entry, sellers compete to sell robots to local final goods producers. I denote $M_s \subseteq \mathcal{M}$ the set of markets that s enters and $S_d \subseteq \mathcal{S}$ the set of active sellers in a market. The sets S_d and M_s are determined in equilibrium, whereas \mathcal{S} and \mathcal{M} are exogenously given.

Robot sellers generate positive profits. Following the approach of Chaney (2008), I assume that these profits are distributed among households in proportion to their labor income.

Households' Preferences. The utility of households $i \in \{r, n\}$ in market d reads:

$$C_d(i) = \left(\sum_{o \in \mathcal{M}} C_{od}(i)^{\frac{\theta-1}{\theta}} \right)^{\frac{\theta}{\theta-1}}, \quad \theta > 1. \quad (3)$$

$C_{od}(i)$ denotes the consumption level of final goods originating from o that households of type i consume in d . The parameter θ is the elasticity of substitution across goods. The disposable income of households of type i is:

$$E_d(i) = w_d(i)\bar{L}_d(i) + s_d(i)\Pi, \quad s_d(i) = \frac{w_d(i)\bar{L}_d(i)}{\sum_{d \in \mathcal{M}} \sum_{i \in \{n, r\}} w_d(i)\bar{L}_d(i)}. \quad (4)$$

$w_d(i)$ denotes the market wage of households of type i and $\bar{L}_d(i)$ is their exogenous labor supply. Households also receive a share $s_d(i)$ of robot sellers' profits, denoted by Π , proportionally to their labor income. The welfare of households of type i can be

expressed as:

$$\mathcal{W}_d = \frac{E_d(i)}{P_d}. \quad (5)$$

P_d denotes the consumer price index in market d .

Final Goods Production. To produce final goods, perfectly competitive firms use robots R_d , routine workers $L_d(r)$, and non-routine workers $L_d(n)$. R_d is a substitute of $L_d(r)$ and a complement to $L_d(n)$. Final goods are produced using the following technology:

$$Y_d = A_d X_d^\beta L_d(n)^{1-\beta}, \quad X_d = (R_d^\eta + L_d(r)^\eta)^{\frac{1}{\eta}}, \quad \beta \in (0, 1), \quad \eta \in (0, 1]. \quad (6)$$

A_d denotes total factor productivity. The elasticity of substitution between R_d and $L_d(r)$ is $1/(1 - \eta)$. Equation (6) is standard in the robot adoption literature and can be derived from a task-based model à la [Acemoglu and Restrepo \(2018\)](#), as shown by [Guerreiro et al. \(2022\)](#). The income share accruing to non-routine labor is $1 - \beta$.

The Robot Industry. Multinational robot sellers make two decisions. First, upon paying an entry cost in terms of local non-routine labor, they choose which markets to serve. These costs capture, among others, the cost of setting up branches. Second, conditional on entry, sellers compete to sell an indivisible bundle of generic robots and integration services to final goods producers. The bundle offered by seller s in market d is called a “product” and denoted by R_{sd} .¹⁰ This bundle is considered non-tradable and produced in the destination market using local non-routine labor.¹¹ Final goods producers in each market combine robot sellers’ products as:

$$R_d = \left(\sum_{s \in S_d} \phi_{sd}^{\frac{1}{\sigma}} R_{sd}^{\frac{\sigma-1}{\sigma}} \right)^{\frac{\sigma}{\sigma-1}}, \quad \sigma > 1. \quad (7)$$

Robot sellers are horizontally and vertically differentiated. Horizontal differentiation stems, among others, from the fact that sellers have their own brand and may open

¹⁰As explained in Section 2.2, robot sales entail a bundle of generic machines, which can potentially perform a variety of activities, and integration services, which adapt these machines to a specific task.

¹¹In Online Appendix E.2, I extend the model and allow generic robots to be produced in one market and exported to another, where they are sold bundled with integration services.

branches in different locations within a market. The elasticity of substitution between the products that they sell is σ .

The source of vertical differentiation is ϕ_{sd} , a demand shifter reflecting the appeal of robot sellers to final goods producers. Since demand shifters are seller-market-specific, robot sellers are allowed to be more attractive in some markets (e.g., the HQ market) compared to others (e.g., markets distant from the HQ). Thus, ϕ_{sd} flexibly captures several frictions that are consistent with gravity, such as home bias in robot demand, the limited knowledge of distant markets by robot sellers, or the presence of coordination costs that increase with distance from the HQ.

Robot sellers compete oligopolistically à la Bertrand in each market.¹² As is standard in the literature of oligopoly in general equilibrium (Atkeson and Burstein, 2008; Gaubert and Itskhoki, 2021), robot sellers take into account the effects of their choices on their market shares and those of their competitors, but not on economy-wide variables. Robot sellers' gross and net profits are, respectively:

$$\bar{\pi}_{sd} = (r_{sd} - w_d(n))R_{sd} \quad \text{and} \quad \pi_{sd} = \bar{\pi}_{sd} - w_d(n)f. \quad (8)$$

r_{sd} is the price set by seller s in market d . Aggregate profits are $\Pi = \sum_{d \in \mathcal{M}} \sum_{s \in S_d} \pi_{sd}$.

International Trade. International trade in final goods is subject to iceberg trade costs. The cost of delivering one unit of good from origin o to destination d is $P_{od} = \tau_{od}p_o$, where $\tau_{od} \geq 1$ and the triangle inequality holds. I denote by p_o the producer price index associated with equation (6).

5.2 Equilibrium

Households. Households choose $C_{od}(i)$ to maximize utility in equation (3) subject to the budget constraint given by equation (4). Solving their problem delivers the following expenditure function, which governs bilateral trade flows in final goods between markets:

$$P_{od}C_{od}(i) = \left(\frac{P_{od}^{1-\theta}}{\sum_{o \in \mathcal{M}} P_{od}^{1-\theta}} \right) E_d(i). \quad (9)$$

¹²The results of the counterfactual exercises are robust to assuming Cournot or monopolistic competition, as discussed in Section 7.2.

Final Goods Producers. Final goods producers choose R_d , $L_d(r)$, and $L_d(n)$ to maximize profits. Solving their problem yields the following input demand functions:

$$R_d = \frac{\beta \bar{\iota}_d p_d Y_d}{r_d}, \quad L_d(r) = \frac{\beta(1 - \bar{\iota}_d) p_d Y_d}{w_d(r)}, \quad L_d(n) = \frac{(1 - \beta) p_d Y_d}{w_d(n)}. \quad (10)$$

r_d is the price of robots in market d , while $\bar{\iota}_d$ is the share of X_d^η produced by robots:

$$\bar{\iota}_d = \frac{R_d^\eta}{R_d^\eta + L_d(r)^\eta}. \quad (11)$$

The producer price index associated with equation (6) is:

$$p_d = \frac{\bar{\beta}}{A_d} [\bar{\iota}_d^\eta r_d^{-\eta} + (1 - \bar{\iota}_d)^\eta w_d(r)^{-\eta}]^{-\frac{\beta}{\eta}} w_d(n)^{1-\beta}, \quad \bar{\beta} = \beta^{-\beta} (1 - \beta)^{\beta-1}. \quad (12)$$

Robot Sellers: Pricing. Equations (7) and (10) imply the following robot demand:

$$R_{sd} = \phi_{sd} r_{sd}^{-\sigma} r_d^{\sigma-1} \beta \bar{\iota}_d p_d Y_d. \quad (13)$$

Sellers set r_{sd} to maximize equation (8) given equation (13). Equilibrium prices are:

$$r_{sd} = \frac{\varepsilon_{sd}}{\varepsilon_{sd} - 1} w_d(n). \quad (14)$$

Markups are defined as $\mu_{sd} = \varepsilon_{sd} / (\varepsilon_{sd} - 1)$, where ε_{sd} is the own-price demand elasticity. Under Bertrand competition the demand elasticity reads:

$$\varepsilon_{sd} = \sigma - (\sigma - 1) s_{sd}. \quad (15)$$

The market share of robot seller s in market d , denoted by s_{sd} , is given by:

$$s_{sd} = \frac{\phi_{sd} r_{sd}^{1-\sigma}}{\sum_{s \in S_d} \phi_{sd} r_{sd}^{1-\sigma}}. \quad (16)$$

Equations (14), (15), and (16) describe robot sellers' pricing strategies. Although this system does not have a closed-form solution, it implies that robot sellers with higher ϕ_{sd} have higher market shares, face less elastic demand, and charge higher markups at a given equilibrium. The robot price index associated with equation (7) can be

expressed as:

$$r_d = \left(\sum_{s \in S_d} \phi_{sd} r_{sd}^{1-\sigma} \right)^{\frac{1}{1-\sigma}}. \quad (17)$$

Robot Sellers: Entry. To ensure the uniqueness of the equilibrium of the entry game, I let robot sellers make entry choices in decreasing order of ϕ_{sd} . Equation (8) implies that the profits of each seller are decreasing in the number its competitors. Let j be the last seller who finds it profitable to enter market d , and let j' be the next potential entrant. The following break-even condition must hold in each market:

$$\bar{\pi}_{jd} \geq w_d(n)f > \bar{\pi}_{j'd}. \quad (18)$$

Equation (18) pins down the equilibrium number of robot sellers. Since the realized demand shifters have a market-specific component, the order in which robot sellers enter is allowed to differ by market. Still, robot sellers with higher average appeal enter more markets. In the model, a multinational is a seller present in least two markets.

Market Clearing Conditions. A market equilibrium consists of a vector of prices $\{r_d, w_d(n), w_d(r)\}$ such that households maximize utility, final goods producers and robot sellers maximize profits, and markets clear. The market clearing conditions to be fulfilled in each market are:

$$p_o Y_o = \sum_{d \in \mathcal{M}} \sum_{i \in \{n, r\}} \left(\frac{P_{od}^{1-\theta}}{\sum_{o \in \mathcal{M}} P_{od}^{1-\theta}} \right) E_d(i), \quad (19)$$

$$\bar{L}_d(r) = \frac{\beta(1 - \bar{t}_d)p_d Y_d}{w_d(r)}, \quad (20)$$

$$\bar{L}_d(n) = \frac{(1 - \beta)p_d Y_d}{w_d(n)} + R_d + |S_d|f. \quad (21)$$

Equation (19) is the final goods market clearing condition, determining output in each market. Equations (20) and (21) govern the equilibrium of routine and non-routine labor markets, respectively. $|S_d|$ is the number of active sellers in market d . Due to Walras' law, one market clearing condition is redundant. In practice, I select $w_d(n)$ in one market as the numéraire and discard the corresponding market clearing condition.

5.3 The Role of Market Structure in the Robot Industry

This section provides insights into how robot sellers' market entry and pricing choices affect equilibrium outcomes. I proceed in three steps. First, I consider a closed economy with symmetric sellers, for which an analytical solution can be derived. Then, I extend the example to a two-market economy with international trade in final goods. Finally, I argue that the insights of these restricted models continue to hold in the general case with heterogeneous sellers and multiple markets. Derivations are in Online Appendix E.3.

Symmetric Sellers and Closed Economy. Let $|\mathcal{M}| = 1$ and $\phi_{sd} = \phi$. Variables' subscripts can be omitted. Sellers' prices admit the following closed-form solution:

$$r = \frac{\varepsilon}{\varepsilon - 1} w(n), \quad \varepsilon = \sigma - (\sigma - 1)s, \quad s = \frac{1}{|S|}. \quad (22)$$

Let $\eta = 1$ for simplicity but without loss of generality and $w(n)$ be the numéraire. The industry-level robot price and final goods price index read:

$$\tilde{r} = |S|^{\frac{1}{1-\sigma}} \phi^{\frac{1}{1-\sigma}} r, \quad p = \frac{\bar{\beta}}{A} \tilde{r}^\beta. \quad (23)$$

Notice that $\eta = 1$ implies $\tilde{r} = w(r)$. Suppose that a new robot seller enters this economy. Treating the number of sellers as a continuous variable for simplicity, equation (22) implies that entry reduces incumbents' prices:

$$\frac{\partial r}{\partial |S|} \frac{|S|}{r} = \frac{1 - \sigma}{\varepsilon(\varepsilon - 1)|S|} < 0. \quad (24)$$

Equation (23) implies that entry also reduces the industry-level robot price and final goods price index:

$$\frac{\partial \tilde{r}}{\partial |S|} \frac{|S|}{\tilde{r}} = \frac{1}{1 - \sigma} + \frac{1 - \sigma}{\varepsilon(\varepsilon - 1)|S|} < 0, \quad \frac{\partial p}{\partial |S|} \frac{|S|}{p} = \frac{\beta}{1 - \sigma} + \frac{\beta(1 - \sigma)}{\varepsilon(\varepsilon - 1)|S|} < 0. \quad (25)$$

As a result, robot demand and total production Y increase, and so do wage and income inequality, defined as $w(n)/w(r)$ and $E(n)/E(r)$ respectively, because $w(r)$ decreases at the same rate of \tilde{r} . Figure 3 provides a numerical example, treating $|S|$ as an integer.

Figure 3. ENTRY IN THE ROBOT INDUSTRY - CLOSED ECONOMY

Note: I simulate an economy consisting of one market initially hosting two symmetric robot sellers. I set $\bar{L}(n) = \bar{L}(r) = 1$, $A = 0.1$, and choose model parameters to match those in Section 6. I set $w_H(n) = 1$ as the numéraire. I progressively increase the number of robot sellers, recompute the equilibrium allocation each time, and show the effects of entry on different outcomes.

Symmetric Sellers and Two-Market Economy. While keeping $\phi_{sd} = \phi$ and $\eta = 1$, I now let $|\mathcal{M}| = 2$ and denote markets by Home (H) and Foreign (F), respectively. Let $w_H(n)$ be the numéraire. Suppose that new sellers enter Home. Since equations (22) and (23) continue to hold in the Home market, entry delivers similar effects to those described in the closed-economy case in that market.

What happens in Foreign? Because markets are connected via international trade in final goods, a reduction in p_H makes all households increase imports from Home as per equation (9), reducing the total output of Foreign. However, by reducing the cost of imported goods, entry in Home increases the welfare of all households in Foreign. Figure 4 provides a numerical example, treating again $|S|$ as an integer. The top panels show the effects in Home, while the bottom ones the effects in Foreign.

Figure 4. ENTRY IN THE ROBOT INDUSTRY - OPEN ECONOMY

Note: I simulate an economy consisting of two markets, Home and Foreign, initially hosting two symmetric robot sellers each. I set $\bar{L}_d(i) = 1$ for all (i, d) , $A_d = 0.1$ for all d , and $\tau_{od} = 1$ if $o = d$ and $\tau_{od} = 1.05$ if $o \neq d$. I choose model parameters to match those in Section 6. I set $w_H(n) = 1$ as the numéraire. I progressively increase the number of robot sellers in Home, recompute the equilibrium allocation each time, and show the effects of entry in Home on different outcomes in Home and Foreign.

The General Case. While analytically convenient, sellers' symmetry is not necessary to generate the predictions in Figures 3 and 4. If robot sellers enter in decreasing order of ϕ_{sd} , the same patterns persist. The patterns in Figure 4 also apply if $|\mathcal{M}| > 2$, though the impact of entry in a single market on the rest of the world is more diluted.

Taking stocks, the model predicts that the entry of new sellers in a market boosts competition, leading to an increase in robot adoption and output in that market. Given the non-neutrality of robots, these gains are not evenly distributed across workers with different skill levels. Workers that are complementary to robots benefit from the entry of new robot sellers, while workers that are substitutes to robots are worse off. When markets are linked via international trade, entry in one market comes at the expense of production in other locations.

6 Quantification

This section discusses estimation, identification, and model fit.

6.1 Empirical Implementation

Market Definition. Bringing the model to the data requires defining the geographical boundaries of the markets where robot sellers compete. In practice, I aggregate the original 45 countries into larger markets using a K-means algorithm. The purpose of the aggregation is twofold. First, it accounts for the fact that robot sellers may use branches in one country to serve adjacent ones, which may happen especially in small countries within the same geographical area (e.g., Belgium and the Netherlands). Second, it reduces the dimensionality of the robot sellers' entry problem while preserving size differences across markets.

The algorithm merges countries with similar latitude and longitude and belonging to the same continent and creates 12 markets. I choose this number to balance between interpretable clusters and dimensionality reduction. The merged markets inherit the average characteristics of the countries belonging to them, and I sum the number of branches across countries by seller before computing market shares.

Online Figure A.6 shows the clustering procedure outcome. The European continent is divided into three markets approximately corresponding to eastern countries (e.g. Hungary and Romania), western-northern countries (e.g., Germany and Sweden), and central-southern countries (e.g., Italy and France). Asia is divided into two markets. The first includes China and India, and the second Japan and South Korea. South America is also divided into two markets, one including central countries (e.g., Mexico and Colombia) and one made of central-southern ones (e.g., Brazil and Argentina). Australia and New Zealand belong to the same market, whereas the US, Canada and South Africa constitute separate ones.

Exogenous Variables. The model features the following exogenous variables: the number of routine workers, $\bar{L}_d(r)$, the number of non-routine workers, $\bar{L}_d(n)$, the productivity of the final goods producers, A_d , and bilateral trade costs, τ_{od} .

The first three variables come from the WDI database of the World Bank. I measure $\bar{L}_d(r)$ using total employment in agriculture and manufacturing and $\bar{L}_d(n)$ using total employment in the services sector. This approximation is justified by the fact that 99%

of the stock of robots in the IFR data are employed in agriculture and manufacturing. No industrial robots are adopted in services, implying that workers in that sector cannot be replaced by robots. I compute A_d using the weighted average of labor productivity in agriculture, manufacturing, and services, where the weights are given by the employment share of each sector. Trade costs between country pairs, τ_{od} , come from the ESCAP World Bank database.

6.2 Estimation Procedure and Identification

Households' choices depend on the trade elasticity, $1 - \theta$. The choices of final goods producers depend on the elasticity of substitution between robots and routine workers, $1/(1 - \eta)$, and the production share of non-routine workers, $1 - \beta$. Robot sellers' choices are governed by the demand shifters, ϕ_{sd} , the elasticity of substitution between their products, σ , and market-level entry costs, f . I calibrate θ , η , and β in a standard way from previous literature and the data. I use a simulated method of moments (SMM) algorithm to estimate the ϕ_{sd} , σ , and f , which are new in the literature.

Calibration. As is standard in the trade literature, I set $\theta = 5$, implying a trade elasticity of -4 (Head and Mayer, 2014). Following the robot adoption literature (Acemoglu and Restrepo, 2018; Guerreiro et al., 2022), I set $\eta = 1$, implying perfect substitution between robots and routine workers. As a result, routine wages are equalized to local robot prices, determined by competition among robot sellers. I calibrate β to match the average value-added labor share of agriculture and manufacturing in the sample, which yields $\beta = 0.34$.

Simulated Method of Moments. Robot sellers draw ϕ_{sd} from the following log-normal distribution, with mean and variance to be estimated:

$$\phi_{sd} = \exp\{\phi_i + \kappa \text{Log Distance from } HQ_{sd} + \zeta u_{sd}\}, \quad i \in \{\text{Top 4, Rest}\}. \quad (26)$$

The demand shifter of robot seller s in market d is a function of its average appeal, the physical distance of market d from its HQ, and an i.i.d. normally distributed random shock with zero mean and unit variance. To minimize the computational burden of the SMM procedure, instead of estimating the average appeal of each robot seller, I let the top 4 sellers in the data (ABB, Kuka, Fanuc, and Yaskawa) draw demand

shifters from a distribution with a potentially higher mean than the others, i.e., I expect $\hat{\phi}_{\text{Top } 4} \geq \hat{\phi}_{\text{Rest}}$. Consistently with the frictions discussed in Section 4.1, I expect $\hat{\kappa} < 0$. The vector of parameters to be estimated is $\Theta = \{\phi_{\text{Top } 4}, \phi_{\text{Rest}}, \kappa, \zeta, \sigma, f\}$.

The SMM procedure consists of a loop with three nests: an outer loop searching over the vector of parameters Θ , a middle loop solving the model general equilibrium allocation, and an inner loop finding the solution to the robot sellers' problem. For each candidate vector Θ , I draw B matrices of ϕ_{sd} from equation (26),¹³ solve the model at each draw, and compute the model-implied moments $m(\Theta)$ as an average across draws. Then, I match simulated moments to the data ones \bar{m} to minimize the SMM objective function $\mathcal{L}(\Theta) = (m(\Theta) - \bar{m})'W(m(\Theta) - \bar{m})$, being W a weighting matrix.

To solve the model, I extend the solution algorithm developed by [Gaubert and Itskhoki \(2021\)](#) for a two-country economy to a multi-country one. This requires guessing wages for each market, solving the robot sellers' problem in each of them, and iterating until a fixed point is reached. Convergence of the inner loop entails a discrete search over the number of sellers, as per equation (18), and a non-linear search over their prices in equation (14). Convergence of the middle loop is achieved by a linear inversion of equations (19), (20), and (21), which helps to reduce the computational burden of the search. See Online Appendix F for more details.

Identification. I target eight data moments to estimate six parameters. The selected moments are informative about robot sellers' entry choices, their sales, strength of competition, and robot adoption. I assign equal weight to each of them.

Although the structural parameters are jointly estimated, each of them is informed in an intuitive way by distinct targeted moments. The parameter $\phi_{\text{Top } 4}$ is used to match the average log number of markets entered by the top 4 robot sellers and their average market shares, whereas ϕ_{Rest} helps matching those of the other robot sellers. All else equal, higher values of both parameters translate into more entered markets and higher market shares. The parameter κ is chosen to replicate the average log distance between the robot sellers' HQ and the markets they enter, while ζ aids matching the standard deviation of the distribution of market shares across robot sellers. A higher κ reduces robot sellers' appeal in more distant markets, whereas a higher ζ makes the realized demand shifters more sensitive to i.i.d. shocks and less to fundamentals.

I choose σ to match the average log stock of robots in the data. Identification rests

¹³I use $B = 200$. I draw normally distributed i.i.d. shocks u_{sd} using Sobol sequences to cover the support of the normal distribution more efficiently than if points were randomly drawn ([Train, 2009](#)).

on the fact that all else equal, higher σ translates into lower markups, lower prices, and a higher number of robots adopted.¹⁴ Finally, f is used to match the average log number of robot sellers per market. A higher f reduces the number of entrants.

6.3 Estimation Results

Model Parameters. Table 2 reports the calibrated and estimated parameter values.

Table 2. SUMMARY OF THE MODEL PARAMETERS

| Parameter | Description | Value | 95% CI | Source/Target |
|-------------------|--|-------|----------------|---|
| <i>Calibrated</i> | | | | |
| θ | Trade Elasticity | 5.00 | | Head and Mayer (2014) |
| β | Income Share of X_d | 0.34 | | WDI |
| η | $L_d(r)$ vs R_d Elasticity | 1.00 | | Guerreiro et al. (2022) |
| <i>Estimated</i> | | | | |
| ϕ_H | Average Demand Shifters (Top 4) | 3.26 | [2.39, 4.35] | Mean Log Markets and Mkt Shares (Top 4) |
| ϕ_L | Average Demand Shifters (Rest) | 2.03 | [1.43, 3.10] | Mean Log Markets and Mkt Shares (Rest) |
| κ | Elasticity to Dist. from HQ | -0.91 | [-1.13, -0.86] | Mean Log Dist. from HQ |
| ζ | Demand Shifters St. Dev. | 1.81 | [1.20, 2.11] | St. Dev. Market Shares |
| f | Market-Level Entry Costs | 1.75 | [1.23, 2.53] | Mean Log No. of Sellers by Market |
| σ | Elasticity of Substitution b/ween R_{sd} | 3.84 | [2.88, 6.43] | Mean Log Stock of Robots |

Note: The table contains the values of the parameters of the model. The top panel reports the value of the parameters calibrated without solving the model. The bottom panel contains those estimated by the SMM procedure. 95% bootstrap confidence intervals (CI) in parenthesis are computed using the method of Bernard et al. (2022), which I describe in Online Appendix F.2.

As expected, the top 4 robot sellers have a higher average appeal than the others, though the 95% confidence intervals around the two estimates partially overlap. Appeal declines with distance from the seller’s HQ, consistent with gravity in Section 4.1. A value of κ close to minus one is in line with estimates from the international trade literature on the elasticity of bilateral trade flows to distance (Head and Mayer, 2014).

On average, entry costs amount to about 20% of robot sellers’ revenues. Positive entry costs align with the fact described in Section 4.2 that only a subset of robot sellers are active in each market. The estimated value of σ implies a markup of approximately 42% at the average sample market shares, with a standard deviation of 17%. This number falls within the range provided by the literature in other industries (De Loecker et al., 2020).

¹⁴An interesting direction for future research is to compile firm- and product-level data on robot prices and quantities and exploit exogenous variation to estimate this elasticity.

Model Fit. Table 3 shows that the model accurately matches the targeted moments.

Table 3. MODEL FIT ON TARGETED MOMENTS

| Description | Data Moments | Simulated Moments |
|-----------------------------------|--------------|-------------------|
| Mean Log No. of Markets (Top 4) | 2.29 | 2.32 |
| Mean Log No. of Markets (Rest) | 2.07 | 2.12 |
| Mean Market Share (Top 4) | 0.17 | 0.18 |
| Mean Market Share (Rest) | 0.12 | 0.09 |
| Mean Log Dist. from HQ | 9.01 | 9.07 |
| St. Dev. Market Shares | 0.07 | 0.06 |
| Mean Log No. of Sellers by Market | 1.99 | 1.90 |
| Mean Log Stock of Robots | 10.30 | 10.30 |

Note: The table reports the data moments targeted by the SMM procedure and the simulated ones implied by the estimated model.

The model also replicates moments not targeted during the SMM procedure, as shown in Table 4. The rows show seller or market-level outcomes, whereas the columns report their values in the data and as implied by the model. As shown by the last column, the null hypothesis of equal means cannot be rejected for any outcome.

Table 4. MODEL FIT ON NON-TARGETED MOMENTS

| Description | Data Moments | Simulated Moments | P-value |
|---------------------------------|--------------|-------------------|---------|
| Log Sales _s | 5.87 | 6.33 | 0.48 |
| HHI _d | 0.33 | 0.40 | 0.28 |
| Log GDP per capita _d | 10.0 | 11.4 | 0.50 |
| Log Export Values _d | 10.6 | 11.2 | 0.76 |

Note: Each row contains a seller (*s*) or market-level (*d*) outcome. The first column reports average values in the data. The second column shows model-implied average values for each outcome. Averages are computed across sellers or markets. The last column is the p-value associated with the null hypothesis that data and model-implied moments have equal means.

Finally, the model replicates the dispersion in robot prices across markets observed in the data. The correlation between the model-implied robot prices calculated using equation (17) and the import prices (unit values) obtained from the BACII dataset equals 84%. Overall, these results support the reliability of the model in capturing salient features of the robot industry and the global economy.

7 A Tax on Robot Adoption

This section discusses the effects of policies aimed at protecting workers displaced by robots.

7.1 Design and Implementation

The Debate. Concerns about workers' displacement have sparked discussions about regulating robots (Shiller, 2017; Acemoglu and Johnson, 2023). One widely debated proposal is a tax on robot adoption. This policy was discussed in 2017 by the EU Parliament as part of broader reforms to mitigate the adverse effects of automation on routine workers.¹⁵ This idea has since sparked research about the taxation of robots (Guerreiro et al., 2022; Thuemmel, 2022; Costinot and Werning, 2023).¹⁶

The ongoing debate focuses on how a robot tax affects robot-adopting firms and the labor market. Responses from the supply side are largely overlooked. In this section, I contribute to this debate by evaluating how multinational robot sellers would respond to a robot tax and how their responses would shape its outcomes.

Introducing a Tax in the Model. In line with previous literature, I consider the introduction a value-added robot tax paid by robot adopters. Let $t_d \in (0, 1)$ if $d \in \text{EU}$ and 0 otherwise. The new price of robots can be expressed as:

$$r_d = \frac{\beta \bar{t}_d p_d Y_d}{(1 + t_d) R_d}. \quad (27)$$

Wage equalization between robots and routine workers requires $w_d(r) = (1 + t_d)r_d$. Equation (13) can be modified as:

$$R_{sd} = \phi_{sd} r_{sd}^{-\sigma} r_d^{\sigma-1} \frac{\beta \bar{t}_d p_d Y_d}{1 + t_d}. \quad (28)$$

A tax reduces the quantity of robots that final users demand, shrinking the effective size of local robot markets. A tax generates revenues $T_{EU} = \sum_{d \in \mathcal{M}} \mathbb{1}\{d \in \text{EU}\} t_d r_d R_d$, which are distributed as a lump-sum payment to EU households.

¹⁵See https://www.europarl.europa.eu/doceo/document/JURI-PR-582443_EN.pdf?redirect for the full proposal of the Committee on Legal Affairs of the European Parliament.

¹⁶This literature shows that when lump-sum transfers are unfeasible (e.g., because the worker type is unobserved), it is optimal to tax robots to redistribute income towards routine workers.

Counterfactual Scenarios. I consider two counterfactual scenarios. In the first, I assume that robot sellers are unable to adjust their entry choices and markups once the tax is implemented. This scenario mimics the standard approach in the literature (Humlum, 2021; Guerreiro et al., 2022; Thuemmel, 2022; Costinot and Werning, 2023; Beraja and Zorzi, 2025).

In the second scenario, I allow robot sellers to change the set of markets they serve and the markups they charge in each market. All else equal, responses along these margins may amplify or attenuate the effects of a tax. On the one hand, if robot prices strongly respond to local competition, robot sellers’ market entry and exit choices may magnify the effects of taxing robot adopters. On the other, robot sellers’ ability to change variable markups, implying imperfect pass-through, may generate attenuation.

I consider a 5% robot tax as the baseline. This tax rate aligns with the short-run optimal tax estimated for the US by Guerreiro et al. (2022). Online Appendix F.3 describes the algorithm used to perform the counterfactuals.

7.2 Results

The Effects in the EU. Table 5 shows the effects of a 5% EU-wide value-added tax on robot adoption in the average EU market. All outcomes are presented as percentage changes relative to the baseline scenario without the tax.

In the first scenario, the number of robot sellers and their markups remain unchanged by design. Final goods producers experience a 5.2% increase in robot prices, leading to a 4.8% reduction in robot demand. Accordingly, production costs rise by 1.9% and output decreases by 1.7%. Consumer prices increase by 0.6%. Income inequality is reduced by 4.7%, with routine households experiencing a 3.3% welfare gain and non-routine households experiencing a 1.5% welfare loss due to their different substitutability with robots.

In the second scenario, the tax shrinks the size of the robot market and leads to a 2.2% reduction in the number of robot sellers. Exit induces an endogenous reallocation of market shares among incumbents, generating a 0.2% increase in the average markup, denoted as $\bar{\mu}_d = \frac{1}{|S_d|} \sum_{s \in S_d} \mu_{sd}$. This increase puts upward pressure on the other prices. Robot prices increase by 5.1% more than in the first scenario, generating a 16% stronger reduction in robot adoption. Producer prices increase by 1.3% more than in the first scenario, while output decreases by 32.1% more. Consumer prices also rise by 36.7% more than in the first case. Income inequality is reduced by 6.9% more, with 11.2%

Table 5. THE EFFECTS OF AN EU-WIDE ROBOT TAX IN THE EU

| Outcome | Variable | First Scenario | Second Scenario | % Change |
|---------------------------------------|--------------------|----------------|-----------------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | 0.000% | -2.287% | |
| Markups | $\bar{\mu}_d$ | 0.000% | 0.239% | |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 5.247% | 5.519% | 5.184% |
| Robot Stock | R_d | -4.892% | -5.675% | 16.006% |
| Producer Price Index | p_d | 1.921% | 1.947% | 1.353% |
| Output | Y_d | -1.787% | -2.362% | 32.177% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.669% | 0.915% | 36.771% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 3.345% | 2.968% | -11.271% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -1.577% | -2.290% | 45.212% |
| Income Inequality | $E_d(n)/E_d(r)$ | -4.763% | -5.094% | 6.949% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

smaller welfare gains for routine households and 45.2% larger welfare losses among non-routine households.

Comparing outcome changes between scenarios suggests that ignoring multinational robot sellers' responses leads to underestimating the aggregate and distributional effects of a tax in the average EU market by about 20%. In terms of policy implications, the results suggest that a welfare-maximizing European planner should set lower robot taxes when robot sellers endogenously respond to it.

The Effects Outside the EU. Since markets are linked via international trade, a tax also produces effects outside the EU. Table 6 shows the effects of a 5% EU-wide value-added tax on robot adoption in the average non-EU market.

An EU-wide robot tax makes EU final goods more expensive, leading EU and non-EU households to shift their expenditures towards non-EU goods. This demand shift prompts non-EU final goods producers to increase output by using more robots. In the first scenario, the average non-EU market sees a 0.8% rise in both robot adoption

and output. The consumer price index goes up by 0.6%, resulting in a welfare loss of 0.4% for routine and non-routine households.

In the second scenario, although there is some entry into non-EU markets, the exit of robot sellers from the EU results in a 26.4% stronger increase in consumer prices outside the EU. This leads to welfare losses for non-EU households that are twice as large compared to the first scenario. Therefore, ignoring multinational robot sellers' responses to a local tax leads to underestimating the welfare effects of a tax also beyond the domestic border.

Table 6. THE EFFECTS OF AN EU-WIDE ROBOT TAX OUTSIDE THE EU

| Outcome | Variable | First Scenario | Second Scenario | % Change |
|---------------------------------------|--------------------|----------------|-----------------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | 0.000% | 0.050% | |
| Markups | $\bar{\mu}_d$ | 0.000% | -0.003% | |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Stock | R_d | 0.837% | 0.735% | -12.186% |
| Output | Y_d | 0.835% | 0.717% | -14.132% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.643% | 0.813% | 26.439% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.418% | -0.979% | 133.971% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.418% | -0.979% | 133.652% |
| Income Inequality | $E_d(n)/E_d(r)$ | 0.000% | 0.000% | |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average non-EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

Robustness. Online Tables B.3 and B.4 show that the results are robust to using a 2% or 7% tax rate. As the tax rate increases (decreases), all changes in outcomes relative to an equilibrium without taxes are amplified (reduced). Online Tables B.5 and B.6 show that the direction of the second-scenario effects is robust to assuming Cournot or monopolistic competition.

7.3 Further Discussion

The Role of Gravity. An implication of gravity is that the marginal entrant in each country is the one originating from the furthest location. Therefore, shocks in

any given market disproportionately affect the sales of foreign sellers. Since an EU-wide robot tax reduces market access in the EU, higher exit rates among Asian robot sellers are expected. Online Table B.7 provides evidence for this uneven effect. In an equilibrium with a tax, the average Asian seller serves 1.6% fewer EU markets than in an equilibrium without. By contrast, the average EU seller experiences a lower reduction in the number of EU markets served, equal to 0.7%. Therefore, robot sellers' heterogeneous responses effectively make a robot tax a protectionist measure from the perspective of the EU.

The Role of International Trade in Final Goods. Online Tables B.8 and B.9 compare the second-scenario outcomes in Tables 5 and 6 with those obtained in a counterfactual economy where bilateral trade costs on final goods are 5% lower. Both tables reveal a complementarity between trade costs and robot sellers' responses: the same robot tax produces stronger responses from the supply side when trade costs are lower. This happens because lower trade costs lead to higher sensitivity of households' import shares to changes in prices in equation (9).¹⁷ Consequently, the reallocation of demand for final goods across markets is amplified, and so is the reallocation of robot supply.

Unilateral Versus Multilateral Taxation. Online Table B.10 compares the outcomes in Tables 5 and 6 with those resulting from a worldwide 5% value-added tax on robot adoption. Compared to a unilateral one, a worldwide tax reduces the number of active robot sellers and output everywhere. All routine households experience welfare gains and all non-routine households face welfare losses. In this sense, a multilateral tax may eliminate the incentives for governments to retaliate against or take advantage of unilateral taxes introduced in foreign jurisdictions.

The Distribution of Outcomes Changes within the EU and non-EU. Tables 5 and 6 refer to the average EU and non-EU markets. I inspect the distribution of the outcome changes between markets within the EU and non-EU areas in Online Table B.11. Although there is variation in the magnitude of the changes, their sign is consistent across the different moments of the distribution within each area.

¹⁷This effect should be understood as a local one around the observed trade costs. In the limit case of free trade, final goods prices equalize and households' expenditure shares become fixed.

A Subsidy on Robot Adoption. Following a similar reasoning as for the tax, I examine the implementation of an EU-wide 5% discount on the price of robots paid by final good producers funded by taxing EU households. Online Table B.12 shows the effects in the average EU and non-EU markets, allowing robot sellers to endogenously adjust entry choices and markups once the tax is introduced. As one may expect, all outcomes exhibit the opposite direction compared to Tables 5 and 6.

Additional Margins of Supply-Side Responses. Besides market entry and pricing choices, multinational robot sellers could respond to regulation along additional margins, such as product innovation. If a tax reduces innovation incentives, the contraction in robot supply may be even stronger than in the baseline model, further magnifying outcome differences between models with and without supply-side responses.

The model can be extended to include multi-product robot sellers. For instance, sellers may offer factory-gate robots differentiated in terms of speed and precision. If robot sellers specialize in different products, markets become more segmented, leading to greater concentration. Since robot prices are more sensitive to changes in the number of sellers when there are only a few incumbents (see Figure 3), the exit of robot sellers would cause a stronger increase in markups and prices than in the baseline model.

Therefore, the results presented thus far should be understood as a lower bound to those implied by a richer model that includes additional margins of responses from the supply side.

8 Competition Policy

This section discusses the effects of improving the efficiency of the robot industry.

Addressing Frictions in the Robot Industry. Recent literature has highlighted that, even if confined to specific sectors, market power can have detrimental effects for the economy as a whole (Edmond et al., 2015; De Loecker et al., 2020; Autor et al., 2020; Edmond et al., 2023). In the model presented in Section 5, robot sellers' market power implies a lower level of output than in a competitive economy. In this section, I investigate the effects of policies that mitigate distortions arising from market power by boosting competition among robot sellers.

Counterfactual Scenarios. I evaluate two counterfactual scenarios. In the first, while holding the total number of robot sellers constant, I simulate the effects of a 25% reduction in the entry costs that robot sellers must pay to serve each market. In the second, while holding entry costs fixed, I simulate the arrival of a new top robot seller with HQ in China, the largest country in the world in terms of robot adoption. In each scenario, I study the implications for competition in the robot industry, final goods producers, and households. Details about the solution algorithm are in Online Appendix F.4.

Results. Table 7 shows the results in the average market. I present all outcomes as percentage changes relative to the baseline model equilibrium. Boosting competition among robot sellers reduces markups and prices in all markets. In the first scenario, routine households experience a welfare loss, whereas non-routine households face a welfare increase. In the second counterfactual scenario, where pro-competitive effects are stronger, both types of households are better off. Still, income inequality increases in both scenarios because non-routine workers systematically experience disproportionately larger gains. These findings suggest that distortions in the robot industry are potentially large but their cost is not evenly borne.

Table 7. BOOSTING COMPETITION IN THE ROBOT INDUSTRY

| Outcome | Variable | Lower Market Entry Costs | New Robot Seller |
|---------------------------------------|--------------------|--------------------------|------------------|
| <i>Panel A: Robot Sellers</i> | | | |
| Number of Sellers | S_d | 5.111% | 5.271% |
| Markups | $\bar{\mu}_d$ | -0.324% | -0.395% |
| <i>Panel B: Final Goods Producers</i> | | | |
| Robot Price | r_d | -0.147% | -16.366% |
| Producer Price Index | p_d | -0.014% | -15.980% |
| Output | Y_d | 0.068% | 17.746% |
| <i>Panel C: Households</i> | | | |
| Consumer Price Index | P_d | -0.001% | -18.489% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.142% | 1.576% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | 0.059% | 5.228% |
| Income Inequality | $E_d(n)/E_d(r)$ | 0.204% | 3.310% |

Note: The table summarizes the effects of promoting competition among robot sellers in the average market. The first column shows the results of a 25% worldwide reduction in market-level entry costs. The second column shows the results of the addition of a new robot seller to the set of potential incumbents. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. All outcome changes are relative to the initial equilibrium with the estimated entry costs and actual number of potential incumbents, respectively.

Implications for Optimal Policy. The results presented thus far suggest that a planner that seeks to maximize production efficiency but also protect workers displaced by robots should promote competition among robot sellers and redistribute income towards routine workers. If lump-sum transfers are unfeasible, taxes on robot adoption could be considered.

9 Conclusions

Automation technology enhances productivity but generates job displacement concerns, leading to debates about policies to regulate its adoption. The current debate focuses on the responses of technology adopters and their implications for the labor market. In this paper, I study supply-side adjustments and their role in shaping the outcomes of policy changes. I focus on the global market of industrial robots, an industry where a few multinational enterprises dominate production and sales.

I collect new data on the characteristics and global sales of the leading multinational robot sellers worldwide. I then develop and estimate a quantitative multi-country general equilibrium model that embeds oligopolistic competition among multinational robot sellers into a standard framework for analyzing the labor market effects of robot adoption. Using the model, I show that multinational robot sellers' market entry and pricing responses to policies targeting robot adoption amplify the aggregate and distributional effects of these interventions. To the extent that markets are linked via international trade and multinational activity, the effects of local policies transmit beyond local borders.

Overall, this paper conveys two messages. First, any regulation targeting the diffusion of robots should take into account not just the responses of robot adopters but also consider those of robot sellers. Second, policymakers of different countries may need to coordinate their efforts to avoid unintended ripple effects.

Properly adapted, the theoretical framework developed in this paper can be used to investigate the role of market power in other segments of the automation industry and other global input markets.

Global Robots

Fabrizio Leone

A Figures

Online Figure A.1. MARKET SHARES IN THE GLOBAL ROBOT INDUSTRY

Note: The figure shows market shares in 2021. Since Orbis does not provide a breakdown of sales by sector of activity, I calculated the market shares using the total turnover of the 26 robot sellers registered with the IFR across all their sectors of activity. However, since automation provision is the primary activity of these firms, their total sales are an accurate proxy for their size in the industry.

Online Figure A.2. TOTAL TURNOVER OF TOP 4 PRODUCERS BY SECTOR

Note: The figure compares the total revenues (in billion USD in 2021) of the top 4 robot sellers with the total revenues of the top 4 sellers in the automotive, smartphone, semiconductor, and computer industries in terms of revenues in Orbis. To compile these lists, I used Orbis in the following way: First, I identified the industry code associated with each of the four industries under consideration. Second, I retrieved all firms that reported one of these four codes as their main sector of activity. Third, within each sector, I ranked firms based on their total revenues and selected the top 4.

Online Figure A.3. EXAMPLES OF WEBSITES WITH INFORMATION ABOUT BRANCHES

Example 1: A Branch of Kuka

KUKA Systems North America LLC.

6600 Center Drive
Sterling Heights, MI 48312
USA

 Google Maps

Example 2: A Branch of ABB

TSR Solutions LLC

Contact information

Address:
9490 ASPEN HILL CIR
80124 LONE TREE
United States

Address in Local language:
9490 ASPEN HILL CIR
80124 LONE TREE
United States

List of authorized area

| Product | Robotics |
|------------------|-------------------------------|
| Partnership | ABB Value Provider |
| Channel type | System Integrator |
| Countries Served | United States |
| Product Line | Electrical & electronics (3C) |
| | Robotics |

Note: The figure shows an example of a website containing information about robot sales branches. The typical information displayed is the branch name and address, as in Example 1. Sometimes, additional information like the telephone number, web address, list of countries served, and product lines are reported, as in Example 2.

Online Figure A.4. THE GLOBAL FOOTPRINT OF ROBOT SELLERS

Note: The figure shows the number of robot sellers' branches per country. China, Germany, Japan, South Korea, and the US are the five largest destination countries.

Online Figure A.5. DIFFERENCES BETWEEN ROBOT SELLERS

Note: The left panel of the figure shows the average number of markets served by the top 4 multinational robot sellers versus the other 6 sellers, labeled “Rest”. The right panel of the figure shows the average market shares of the two groups.

Online Figure A.6. MARKET DEFINITION

Note: The figure shows the definition of 12 markets used in the quantitative model. Markets are aggregated using a K-means algorithm that merges countries with similar latitude and longitude and belonging to the same continent. The resulting markets inherit the average of the characteristics of the countries belonging to them.

B Tables

Online Table B.1. GRAVITY IN MARKET ENTRY AND SALES

| Dependent Variables: | $Entry_{s(o)d}$ (1) | $Market\ Share_{s(o)d}$ (2) | $Entry_{s(o)d}$ (3) | $Market\ Share_{s(o)d}$ (4) |
|--|------------------------|--------------------------------|------------------------|--------------------------------|
| $\log Distance\ from\ HQ_{s(o)d}$ | -0.14*** (0.03) | -0.04*** (0.010) | | |
| $Cultural\ Distance\ from\ HQ_{s(o)d}$ | | | 0.05* (0.03) | 0.03*** (0.010) |
| Seller FE | Yes | Yes | Yes | Yes |
| Country FE | Yes | Yes | Yes | Yes |
| Observations | 450 | 214 | 450 | 214 |
| Estimator | OLS | OLS | OLS | OLS |

Note: An observation is a robot seller-destination country pair. In the first and third columns, the dependent variable is a binary indicator equal to 1 if seller s from HQ o enters in country d . In the second and fourth columns, the dependent variable is the market share of seller s from HQ o in country d . $\log Distance\ from\ HQ_{s(o)d}$ is the log of the distance between the two most populated cities of the seller HQ and destination country in kilometers. $Cultural\ Distance\ from\ HQ_{s(o)d}$ is a continuous index of linguistic proximity between the seller HQ and the destination country. Both variables are standardized to have zero mean and unit variance in the sample. Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

Online Table B.2. CONCENTRATION AND MARKET SIZE

| Dependent Variables: | <i>Number of Sellers_d</i> (1) | <i>HHI_d</i> (2) | <i>Number of Sellers_d</i> (3) | <i>HHI_d</i> (4) |
|---------------------------------------|---|-------------------------------|---|-------------------------------|
| Intercept | 4.8*** (0.34) | 0.34*** (0.02) | 4.8*** (0.21) | 0.34*** (0.02) |
| <i>Log GDP per capita_d</i> | | | 1.0*** (0.23) | -0.02 (0.02) |
| <i>Log Population_d</i> | | | 2.2*** (0.24) | -0.09*** (0.02) |
| Observations | 45 | 45 | 45 | 45 |
| Estimator | OLS | OLS | OLS | OLS |

Note: An observation is a destination country. In the first and third columns, the dependent variable is the number of robot sellers active in country d . In the second and fourth columns, the dependent variable is the HHI in country d . *Log GDP per capita_d* is the log GDP per capita in country d (in 2010 USD PPP), whereas *Log Population_d* is the log total population of country d . I standardize both variables to have zero mean and unit variance in the sample. Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

Online Table B.3. THE EFFECTS OF AN EU-WIDE ROBOT TAX IN THE EU - ALTERNATIVE TAX RATES

| Outcome | Variable | Tax = 2% | Tax = 5% | Tax = 7% |
|---------------------------------------|--------------------|----------|----------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | -1.895% | -2.287% | -1.308% |
| Markups | $\bar{\mu}_d$ | 0.172% | 0.239% | 0.098% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 2.284% | 5.519% | 7.731% |
| Robot Stock | R_d | -2.459% | -5.675% | -7.585% |
| Producer Price Index | p_d | 0.798% | 1.947% | 2.854% |
| Output | Y_d | -1.019% | -2.362% | -3.190% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.374% | 0.915% | 1.424% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 1.261% | 2.968% | 3.678% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.967% | -2.290% | -3.379% |
| Income Inequality | $E_d(n)/E_d(r)$ | -2.193% | -5.094% | -6.793% |

Note: The table summarizes the effects of different EU-wide value-added taxes on robot adoption in the average EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.4. THE EFFECTS OF AN EU-WIDE ROBOT TAX OUTSIDE THE EU
- ALTERNATIVE TAX RATES

| Outcome | Variable | Tax = 2% | Tax = 5% | Tax = 7% |
|---------------------------------------|--------------------|----------|----------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | 0.097% | 0.050% | 0.033% |
| Markups | $\bar{\mu}_d$ | -0.006% | -0.003% | 0.000% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 0.473% | 1.219% | 1.661% |
| Robot Stock | R_d | 0.296% | 0.735% | 1.009% |
| Producer Price Index | p_d | 0.476% | 1.218% | 1.660% |
| Output | Y_d | 0.286% | 0.717% | 0.986% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.311% | 0.813% | 1.086% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.369% | -0.978% | -1.254% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.365% | -0.979% | -1.256% |
| Income Inequality | $E_d(n)/E_d(r)$ | 0.004% | -0.000% | -0.002% |

Note: The table summarizes the effects of different EU-wide value-added taxes on robot adoption in the average non-EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.5. THE EFFECTS OF AN EU-WIDE ROBOT TAX IN THE EU - ALTERNATIVE MARKET STRUCTURE

| Outcome | Variable | Bertrand | Cournot | Monopolistic Competition |
|---------------------------------------|--------------------|----------|---------|--------------------------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | -2.287% | -0.178% | -3.318% |
| Markups | $\bar{\mu}_d$ | 0.239% | 0.030% | 0.823% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 5.519% | 5.289% | 5.117% |
| Producer Price Index | p_d | 1.947% | 1.958% | 1.445% |
| Output | Y_d | -2.362% | -2.068% | -0.286% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.915% | 0.986% | 0.824% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 2.968% | 2.563% | 2.818% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -2.290% | -2.327% | -2.598% |
| Income Inequality | $E_d(n)/E_d(r)$ | -5.094% | -4.768% | -5.261% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average EU market under alternative market structure assumptions (Bertrand competition, Cournot competition, and monopolistic competition). Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.6. THE EFFECTS OF AN EU-WIDE ROBOT TAX OUTSIDE THE EU
- ALTERNATIVE MARKET STRUCTURE

| Outcome | Variable | Bertrand | Cournot | Monopolistic Competition |
|---------------------------------------|--------------------|----------|---------|--------------------------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | 0.050% | 0.006% | 0.078% |
| Markups | $\bar{\mu}_d$ | -0.003% | -0.001% | -0.015% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 1.219% | 1.262% | 0.949% |
| Producer Price Index | p_d | 1.218% | 1.262% | 0.957% |
| Output | Y_d | 0.717% | 0.042% | 2.238% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.813% | 0.737% | 0.589% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.978% | -0.650% | -0.573% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.979% | -0.649% | -0.562% |
| Income Inequality | $E_d(n)/E_d(r)$ | -0.000% | 0.000% | 0.012% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average non-EU market under alternative market structure assumptions (Bertrand competition, Cournot competition, and monopolistic competition). Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. In the first two columns, outcomes changes are relative to the initial equilibrium without tax. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.7. THE EFFECTS OF AN EU-WIDE
ROBOT TAX ON DIFFERENT SELLERS

| HQ | Change in the Number of EU Markets |
|--------|------------------------------------|
| Europe | -0.735% |
| Asia | -1.667% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average non-EU market for sellers headquartered in different areas. All outcomes changes are relative to the initial equilibrium without tax.

Online Table B.8. THE COMPLEMENTARITY BETWEEN MARKET STRUCTURE AND TRADE COSTS - AVERAGE EU MARKET

| Outcome | Variable | Actual Trade Costs | Low Trade Costs | % Change |
|---------------------------------------|--------------------|--------------------|-----------------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | -2.287% | -2.763% | 20.813% |
| Markups | $\bar{\mu}_d$ | 0.239% | 0.375% | 56.904% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 5.519% | 5.547% | 0.507% |
| Robot Stock | R_d | -5.675% | -6.478% | 14.150% |
| Producer Price Index | p_d | 1.947% | 1.945% | -0.103% |
| Output | Y_d | -2.362% | -2.492% | 5.504% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.915% | 0.888% | -2.951% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 2.968% | 3.072% | 3.504% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -2.290% | -2.232% | -2.533% |
| Income Inequality | $E_d(n)/E_d(r)$ | -5.094% | -5.134% | 0.785% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. I compare two scenarios. In the first, I leave trade costs at their level observed in the data. In the second, trade costs between all country pairs are reduced by 5%. In the first two columns, outcomes changes are relative to the initial equilibrium with actual trade costs. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.9. THE COMPLEMENTARITY BETWEEN MARKET STRUCTURE AND TRADE COSTS - AVERAGE NON-EU MARKET

| Outcome | Variable | Actual Trade Costs | Low Trade Costs | % Change |
|---------------------------------------|--------------------|--------------------|-----------------|----------|
| <i>Panel A: Robot Sellers</i> | | | | |
| Number of Sellers | S_d | 0.050% | 0.051% | 2.000% |
| Markups | $\bar{\mu}_d$ | -0.003% | -0.004% | 33.333% |
| <i>Panel B: Final Goods Producers</i> | | | | |
| Robot Price | r_d | 1.219% | 1.053% | -13.618% |
| Robot Stock | R_d | 0.735% | 0.792% | 7.755% |
| Producer Price Index | p_d | 1.218% | 1.053% | -13.547% |
| Output | Y_d | 0.717% | 0.774% | 7.950% |
| <i>Panel C: Households</i> | | | | |
| Consumer Price Index | P_d | 0.813% | 0.653% | -19.680% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.978% | -0.670% | -31.493% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.979% | -0.670% | -31.563% |
| Income Inequality | $E_d(n)/E_d(r)$ | -0.000% | 0.000% | |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption in the average non-EU market. Panel A shows the effects on robot sellers. Panel B shows the effects on final goods producers. Panel C shows the effects on households. I compare two scenarios. In the first, I leave trade costs at their level observed in the data. In the second, trade costs between all country pairs are reduced by 5%. In the first two columns, outcomes changes are relative to the initial equilibrium with actual trade costs. The last column displays the percentage change in each outcome between the second and first scenario.

Online Table B.10. AN EU-WIDE VERSUS A WORLDWIDE ROBOT TAX

| Outcome | Variable | EU-wide Tax | Worldwide Tax |
|------------------------|--------------------|-------------|---------------|
| <i>Panel A: EU</i> | | | |
| Number of Sellers | S_d | -2.287% | -0.451% |
| Markups | $\bar{\mu}_d$ | 0.239% | 0.051% |
| Robot Price | r_d | 5.519% | 5.433% |
| Robot Stock | R_d | -5.675% | -2.046% |
| Producer Price Index | p_d | 1.947% | 2.079% |
| Output | Y_d | -2.362% | 1.172% |
| Consumer Price Index | P_d | 0.915% | 1.726% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 2.968% | 0.422% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -2.290% | -4.394% |
| Income Inequality | $E_d(n)/E_d(r)$ | -5.094% | -4.795% |
| <i>Panel B: Non-EU</i> | | | |
| Number of Sellers | S_d | 0.050% | -0.407% |
| Markups | $\bar{\mu}_d$ | -0.003% | 0.031% |
| Robot Price | r_d | 1.219% | 6.010% |
| Robot Stock | R_d | 0.735% | -4.762% |
| Producer Price Index | p_d | 1.218% | 2.649% |
| Output | Y_d | 0.717% | -1.636% |
| Consumer Price Index | P_d | 0.813% | 1.742% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -0.978% | 0.964% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | -0.979% | -3.860% |
| Income Inequality | $E_d(n)/E_d(r)$ | -0.000% | -4.778% |

Note: The table compares the effects of a 5% unilateral (EU-wide) and multilateral (worldwide) value-added tax on robot adoption. Panel A shows the effects in the average EU market. Panel B shows the effects in the average non-EU market. All outcomes changes are relative to the initial equilibrium without tax.

Online Table B.11. THE EFFECTS OF AN EU-WIDE ROBOT TAX WITHIN EU AND NON-EU MARKETS

| Counterfactual | EU | Mean | Q25 | Median | Q75 |
|--|----|---------|---------|---------|---------|
| <i>Panel A: Robot Stock, R_d</i> | | | | | |
| First Scenario | 0 | 0.837% | 0.000% | 0.147% | 0.190% |
| First Scenario | 1 | -4.892% | -5.056% | -4.346% | -4.063% |
| Second Scenario | 0 | 0.735% | 0.013% | 0.101% | 0.514% |
| Second Scenario | 1 | -5.675% | -6.853% | -5.727% | -5.377% |
| <i>Panel B: Output, Y_d</i> | | | | | |
| First Scenario | 0 | 0.835% | 0.000% | 0.147% | 0.190% |
| First Scenario | 1 | -1.787% | -1.958% | -1.225% | -0.928% |
| Second Scenario | 0 | 0.717% | 0.004% | 0.101% | 0.375% |
| Second Scenario | 1 | -2.362% | -3.062% | -2.651% | -2.224% |
| <i>Panel C: Welfare Routine, $\mathcal{W}_d(r)$</i> | | | | | |
| First Scenario | 0 | -0.418% | -0.603% | -0.308% | -0.295% |
| First Scenario | 1 | 3.345% | 2.766% | 3.151% | 3.779% |
| Second Scenario | 0 | -0.978% | -1.281% | -1.164% | -0.961% |
| Second Scenario | 1 | 2.968% | 2.587% | 3.453% | 4.719% |
| <i>Panel D: Welfare Non-Routine, $\mathcal{W}_d(n)$</i> | | | | | |
| First Scenario | 0 | -0.419% | -0.603% | -0.308% | -0.296% |
| First Scenario | 1 | -1.577% | -2.129% | -1.762% | -1.163% |
| Second Scenario | 0 | -0.979% | -1.285% | -1.149% | -0.962% |
| Second Scenario | 1 | -2.290% | -2.399% | -1.474% | -1.391% |

Note: The table summarizes the effects of a 5% EU-wide value-added tax on robot adoption the across EU and non-EU markets. Each panel refers to a different outcome, and I compare two scenarios. In the first scenario, robot sellers are unable to adjust their entry choices and markups once the tax is implemented. In the second, they can change the set of markets served and the markups charged in each market. All outcomes changes are relative to the initial equilibrium without tax.

Online Table B.12. THE EFFECTS OF AN EU-WIDE ROBOT SUBSIDY

| Outcome | Variable | Value |
|------------------------|--------------------|---------|
| <i>Panel A: EU</i> | | |
| Number of Sellers | S_d | 0.994% |
| Markups | $\bar{\mu}_d$ | -0.129% |
| Robot Price | r_d | -5.155% |
| Robot Stock | R_d | 8.233% |
| Producer Price Index | p_d | -1.856% |
| Output | Y_d | 2.786% |
| Consumer Price Index | P_d | -0.991% |
| Welfare Routine | $\mathcal{W}_d(r)$ | -1.253% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | 4.013% |
| Income Inequality | $E_d(n)/E_d(r)$ | 5.335% |
| <i>Panel B: Non-EU</i> | | |
| Number of Sellers | S_d | -0.056% |
| Markups | $\bar{\mu}_d$ | 0.005% |
| Robot Price | r_d | -1.041% |
| Robot Stock | R_d | -0.135% |
| Producer Price Index | p_d | -1.042% |
| Output | Y_d | -0.121% |
| Consumer Price Index | P_d | -0.670% |
| Welfare Routine | $\mathcal{W}_d(r)$ | 1.515% |
| Welfare Non-Routine | $\mathcal{W}_d(n)$ | 1.513% |
| Income Inequality | $E_d(n)/E_d(r)$ | -0.002% |

Note: The table summarizes the effects of a 5% EU-wide value-added subsidy on robot adoption in the EU and beyond. Panel A shows the effects in the average EU market. Panel B shows the effects in the average non-EU market. All outcomes changes are relative to the initial equilibrium without subsidy.

C Additional Background

C.1 The Location of Production Facilities

To identify countries in which the top 10 multinational robot manufacturers (see Section 3) have production facilities, I proceed in three steps.

- Using the R package `concordance`,¹⁸ I identify that robots (HS 847959) are

¹⁸Steven Liao, In Song Kim, Sayumi Miyano, Hao Zhang (2020). `concordance`: Product Concordance. R package version 2.0.0. <https://CRAN.R-project.org/package=concordance>

produced by firms in the “Other General Purpose Machinery Manufacturing” industry (NAICS 3339).

- Using Orbis, I construct the global network of subsidiaries of the top 10 robot manufacturers. I identify 1032 subsidiaries in total. Next, I check the main sector of activity of each subsidiary, as indicated by their NAICS code. This information is non-missing for 819 (80%) subsidiaries.
- I select the subsidiaries reporting NAICS 3339 as their main industrial activity in 2021, and I consider them as the manufacturers’ production facilities. Last, compute the number of production facilities per country.

The procedures identifies production facilities in the following countries: Belgium, Canada, China, Czech Republic, Germany, Great Britain, Italy, Japan, Norway, Slovakia, Slovenia, South Korea, Sweden, the Netherlands, and the US. I cross-check this list with information about the export of robots from the BACII dataset. Reassuringly, the correlation between the number of production facilities and the export value of robots at the country level is 55%. The correlation is significant at the 1% level.

C.2 Technological Requirements for Robot Production

Robot production involves three main stages: design, fabrication, and assembly. The design stage has high technological requirements. Fabrication and assembly are capital-intensive activities, and robots are usually assembled by other robots. Three elements suggest that high initial sunk and fixed production costs can help explain the concentration in robot sales documented in Section 3.

- The top 10 robot producers started developing robots around 50 years ago. For instance, ABB launched its first robot in 1978, Fanuc in 1974, Kuka in 1973, and Yaskawa in 1977. The other six firms in the top 10 started producing robots between the end of the 1970s and the beginning of the 1980s. This information comes from the sellers’ websites.
- Using Orbis, I find that the average top 10 robot producer reports a share of R&D expenses over sales equal to 3.5%. For reference, the average non-top 10 producer registered with the IFR reports a share of 2.8%. It is also useful to benchmark this share against that reported by firms in other sectors. To do so, I

compute the share of R&D expenses over sales for the top 500 firms in Orbis in terms of sales, employment, and fixed assets. This set includes Apple, Alphabet, and Microsoft, among others. Notably, no top 10 robot producer belongs to this list. Although the average top 500 firm in Orbis reports 12 times higher sales than the average top 10 robot producer, its share of R&D expenses over sales is equal to 2.9%, which is 6 percentage points lower than that of the average top 10 robot producer.

- Using Orbis Intellectual Property (IP), a Moody’s dataset containing information about patents and their ownership, I find that concentration in sales aligns with concentration in patents.
 - I download from Orbis IP all patents that contain the word “industrial robots” in the title, abstract, or description. Whenever not reported in English, I translate the patent assignee name using the Google Translate R API.¹⁹
 - I match patents to their owners in Orbis. Among the 26 firms registered with the IFR, the top 10 accounting for 90% of global sales also hold 81% of the stock of active patents in 2021. Their patents also receive more citations on average (4 for the top 10 sellers vs. 3.3 for the others) and have longer expiry dates (nine years for the top 10 sellers vs. three years for the others).

C.3 Case Studies about Integration Services

Case studies available on the sellers’ websites illustrate the central role of integration services. The typical case study describes a firm seeking help to automate parts of its production (e.g., stacking crates, handling products, or lifting components), and how a local branch of a robot seller helped the firm by selecting a standardized robot and tailoring it to its needs. I provide three examples below:

- A Swiss firm producing turf wanted to automate the operation of palletizing is harvest. To do so, the company resorted to the help of a Swiss branch of Fanuc who adapted and mounted a robot to the rear of an harvester to facilitate the palletization of turf rolls. Additional details can be found [here](#).

¹⁹See <https://github.com/ropensci/googleLanguageR>.

- A Brazilian meat producer wanted to develop an automated high-speed line for producing and handling simultaneously different types of meat. To achieve this goal, the company contacted a Brazilian branch of ABB, who installed different robots at the meat producer’s plant to pick both light and heavy products and palletizing them. Additional details can be found [here](#).
- A food company approached a US branch of KUKA to automate the process of stacking milk crates on pallets in the cold storage warehouse. The branch selected a suitable robot for the company and customized it to be able to work in a unusually cold environment. Additional details can be found [here](#).

D Data Appendix

D.1 Web Scraping Algorithm

I construct the global sales network of the top 10 multinational robot sellers identified in Section 3 using the following procedure: (1) I access the “Where to Find Us” section on the firms’ websites, where they provide information about their global footprint. Typically, firms list the location of their HQ, sales branches of robots and other products, education and training centers; (2) Using the Python library `Selenium`,²⁰ I web scrape the name and geographical address of each entity listed in that section. Whenever available, I also collect additional information (e.g., product sold and services offered).

Data cleaning involves two steps. First, I separate sales branches where costumers can purchase robots and integration services from entities performing other activities (e.g., training or production centers, consumers’ help desks, and research laboratories). This step is uncontroversial since companies report this information on their website. Second, I distinguish between branches selling robots and providing integration services and those commercializing other products (e.g., precision machinery, engines, generators, drives, and computer systems). This step is straightforward when companies directly report the information on their websites. However, in cases where the information is not explicitly stated, I apply the following conservative rules. First, if the branch name hints at non-robot sales (e.g., contains “electronic provider”), I exclude it from the sample. Second, I exclude branches located in countries where the IFR

²⁰See <https://github.com/seleniumbase/SeleniumBase>.

does not document any robot usage. I keep branches selling both robots and other products.

D.2 Measurement of Market Shares

Information about sales is available for 300 (55%) of the 538 branches that can be found in Orbis. Using this sub-sample, I can compare two measures of market share. The first is based on the number of branches that a seller has in a country, i.e., $s_{sd}^{(1)} = \frac{b_{sd}}{\sum_{s \in S_d} b_{sd}}$. b_{sd} is the number of branches of seller s in country d , and S_d is the set of sellers selling in d . The second measure is based on the sales of the branches that a seller has in a country, i.e., $s_{sd}^{(2)} = \frac{\sum_{b \in B_{sd}} v_{b(s)d}}{\sum_{s \in S_d} \sum_{b \in B_{sd}} v_{b(s)d}}$. $v_{b(s)d}$ denotes sales of branch b belonging to seller s in country d in USD millions. B_{sd} is the set of branches that s has in d . The Pearson correlation between $s_{sd}^{(1)}$ and $s_{sd}^{(2)}$ is 67%***. The Spearman correlation is 53%. The first two columns of Online Table D.1 show that the positive and significant correlation between the two measures is robust to controlling for seller and country fixed effects. Because country fixed effects absorb the denominators of $s_{sd}^{(1)}$ and $s_{sd}^{(2)}$, there is also a positive correlation between the number of branches and sales in (log) levels, as shown by the last two columns. Overall, sellers with more branches also appear to sell more. I prefer $s_{sd}^{(1)}$ to $s_{sd}^{(2)}$ because it can be constructed for more seller-market pairs.

Online Table D.1. Measuring Market Shares

| Dependent Variables: | <i>Mkt Share (Sales)_{sd}</i> (1) | <i>Mkt Share (Sales)_{sd}</i> (2) | <i>Log Sales_{sd}</i> (3) | <i>Log Sales_{sd}</i> (4) |
|--|--|--|--------------------------------------|--------------------------------------|
| <i>Mkt Share (Branches)_{sd}</i> | 0.83*** (0.07) | 0.48** (0.24) | | |
| <i>Log Branches_{sd}</i> | | | 1.1*** (0.19) | 0.77*** (0.25) |
| Country FE | No | Yes | No | Yes |
| Seller FE | No | Yes | No | Yes |
| Observations | 133 | 133 | 133 | 133 |
| R ² | 0.45 | 0.55 | 0.22 | 0.64 |
| Within R ² | | 0.06 | | 0.10 |
| Estimator | OLS | OLS | OLS | OLS |

Note: An observation is a robot seller-destination country pair. *Mkt Share (Sales)_{sd}* is the market share of seller *s* in country *d* based on the sales of its branches. *Mkt Share (Branches)_{sd}* is the market share of seller *s* in country *d* based on its number of branches. *Log Sales_{sd}* are the total sales of the branches of seller *s* in market *d*. *Branches_{sd}* is the number of branches of seller *s* in country *d*. Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

D.3 Data Validation

I validate the own-collected information about global sales networks against three established data sources (IFR, BACII, and Orbis).

- I estimate the following country-level equation:

$$Robots_d = \alpha + \beta Branches_d + \gamma Controls_d + \varepsilon_d.$$

Robots_d is the number of robots in country *d* reported by the IFR. *Branches_d* is the self-collected number of multinational sellers' branches in country *d*. *Controls_d* include Log GDP per capita. ε_d is the error term. Online Table D.2 shows the estimates. *Number of Branches_d* explains 56%-57% of the variation in *Number of Robots_d*.

Online Table D.2. Robots vs Branches

| Dependent Variable: | <i>Robots_d</i> | |
|-----------------------------|---------------------------|-------------------|
| | (1) | (2) |
| <i>Branches_d</i> | 0.62*** (0.21) | 0.63*** (0.21) |
| Controls | No | Yes |
| Observations | 45 | 45 |
| R ² | 0.56 | 0.57 |
| Estimator | OLS | OLS |

Note: An observation is a destination country. *Robots_d* is the number of robots in country *d*. *Branches_d* is the number of branches in country *d*. Controls include include the GDP per capita (in 2010 USD PPP). Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

Additionally, $Corr(Branches_d, Robot\ Stock_d) = 75\%^{***}$.

- I estimate the following equation:

$$Trade\ in\ Robots_{od} = \beta Branches_{od} + \gamma Controls_{od} + FE_o + FE_d + \varepsilon_{od}.$$

Trade in Robots_{od} is the export value of robots (HS 847950) from *o* to *d* in million current USD reported in the BACI dataset. *Branches_{od}* is the self-collected number of branches that multinational sellers headquartered in *o* open in *d*. *Controls_{od}* include Log of bilateral distance in kilometers. *FE_o* are origin fixed effects, *FE_d* destination fixed effects, and ε_{od} the error term. Online Table D.3 shows the estimates. Even after controlling for origin and destination fixed effects, as well as bilateral distance, *Number of Branches_{od}* explains 61% of the within R^2 of *Trade in Robots_{od}*.

Online Table D.3. Trade vs Branches

| Dependent Variable: | <i>Trade in Robots_{od}</i> | | |
|------------------------------|-------------------------------------|------------------|------------------|
| | (1) | (2) | (3) |
| <i>Branches_{od}</i> | 10.5*** (3.8) | 11.8*** (3.9) | 11.3*** (3.9) |
| Origin FE | No | Yes | Yes |
| Destination FE | No | Yes | Yes |
| Controls | No | No | Yes |
| Observations | 133 | 133 | 133 |
| R ² | 0.60 | 0.75 | 0.75 |
| Within R ² | | 0.61 | 0.61 |
| Estimator | OLS | OLS | OLS |

Note: An observation is an origin-destination country pair. *Trade in Robots_{od}* is the export value of robots (HS 847950) from *o* to *d* in million current USD. *Branches_{od}* is the self-collected number of branches that multinational sellers headquartered in *o* open in *d*. Controls include Log of bilateral distance in kilometers. Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

Additionally, $Corr(Branches_{od}, Trade\ in\ Robots_{od}) = 77\%^{***}$.

- I estimate the following seller-country level equation:

$$B_{s(o)d} = \beta S_{s(o)d} + FE_s + FE_d + \varepsilon_{s(o)d}.$$

$B_{s(o)d}$ is either an indicator equal to 1 if multinational seller *s* from HQ *o* has at least one branch in country *d* (extensive margin) or the number of branches that *s* has in country *d* (intensive margin). $S_{s(o)d}$ is either an indicator equal to 1 if seller *s* from HQ *o* has at least one subsidiary in country *d* (extensive margin) or the number of subsidiaries that *s* has in country *d* (intensive margin). Subsidiaries include those unrelated to robots, as reported in Orbis. FE_s and FE_d are seller and country fixed effects, and $\varepsilon_{s(o)d}$ the error term. Online Table D.4 shows the estimates. The presence of sales branches is positively correlated with the presence of subsidiaries, even after controlling for FE_s and FE_d .

Online Table D.4. Branches vs Subsidiaries

| Dependent Variables: | <i>Branch Dummy_{sd}</i> | <i>Branches_{sd}</i> | | |
|--------------------------------------|----------------------------------|------------------------------|-------------------|------------------|
| | (1) | (2) | (3) | (4) |
| <i>Subsidiary Dummy_{sd}</i> | 0.44*** (0.03) | 0.32*** (0.04) | | |
| <i>Subsidiaries_{sd}</i> | | | 0.16*** (0.06) | 0.10** (0.05) |
| Country FE | No | Yes | No | Yes |
| Seller FE | No | Yes | No | Yes |
| Observations | 920 | 920 | 155 | 155 |
| R ² | 0.24 | 0.57 | 0.14 | 0.52 |
| Within R ² | | 0.11 | | 0.05 |
| Estimator | OLS | OLS | OLS | OLS |

Note: An observation is a robot seller-destination country pair. *Branch Dummy_{s(o)d}* is an indicator equal to 1 if seller s from HQ o has at least one branch in country d . *Subsidiary Dummy_{s(o)d}* is an indicator equal to 1 if seller s from HQ o has at least one subsidiary in country d . *Branches_{s(o)d}* is the number of branches that seller s from HQ o has at least one branch in country d . *Subsidiaries_{s(o)d}* is the number of subsidiaries that seller s from HQ o has at least one branch in country d . Heteroscedasticity-robust standard errors in parenthesis. Significance levels: *** 0.01, ** 0.05, * 0.1.

Additionally, $\text{Corr}(\text{Subsidiaries}_{s(o)d}, \text{Branches}_{s(o)d}) = 48\%^{***}$ at the extensive margin and $38\%^{***}$ at the intensive margin.

E Theoretical Appendix

E.1 Multi-Branch Multinational Robot Sellers

I extend the model presented in Section 5 to feature multi-branch multinational robot sellers. While this model delivers similar predictions as the baseline one, it provides a micro-foundation for the fact that sellers that open more branches in a market also sell more robots.

Nested Robot Demand. I assume that seller s in market d supplies an indivisible bundle of generic robots and integration services, which I refer to as a “product” and define by \tilde{R}_{sd} . In turn, this product is a bundle of the varieties offered by branches b of

seller s in market d , which I denote $R_{b(s)d}$. Formally, R_d used by final goods producers defined as:

$$R_d = \left(\sum_{s \in S_d} \phi_{sd}^{\frac{1}{\sigma}} \check{R}_{sd}^{\frac{\sigma-1}{\sigma}} \right)^{\frac{\sigma}{\sigma-1}}, \quad \check{R}_{sd} = \left(\sum_{b \in B_{sd}} R_{b(s)d}^{\frac{\rho-1}{\rho}} \right)^{\frac{\rho}{\rho-1}}, \quad \rho \geq \sigma > 1. \quad (\text{E.1})$$

Notation follows from equation (7). Combining the first-order conditions of equations (6) and (E.1), the demand faced by each branch can be expressed as:

$$R_{b(s)d} = \phi_{sd} r_{b(s)d}^{-\rho} \check{r}_{sd}^{\rho-\sigma} r_d^{\sigma-1} \beta \bar{t}_d p_d Y_d. \quad (\text{E.2})$$

$r_{b(s)d}$ is the price charged by branch b of seller s in market b , r_{sd} is the price index of seller s in market d , and r_d is the market-level price of robots. Branches internalize the effect of their choices on the sector price index r_d but not on economy-wide variables.

Profit Maximization. Sellers choose the number of branches to open in each market and the prices charged by each of their branches. Let B_{sd} be the set of branches that s operates in d . I assume that seller s in market d solves the following problem:

$$\max_{\{r_{sd}, b_{sd}\} \geq 0} \sum_{b \in B_{sd}} (r_{b(s)d} - w_d(n)) R_{b(s)d} - w_d(n) \frac{b_{sd}^{1+\frac{1}{\lambda}}}{1+\frac{1}{\lambda}} - w_d(n) f, \quad \lambda > 0 \quad (\text{E.3})$$

$$\text{s.t. equation (E.2)} \quad (\text{E.4})$$

$b_{sd}^{1+\frac{1}{\lambda}} / (1 + \frac{1}{\lambda})$ is a convex cost of opening branches.

Equilibrium Conditions. Since demand shifters ϕ_{sd} are seller-market-specific and retail costs $w_d(n)$ market-specific, sellers equalize the markups charged by their branches, which gives rise to a symmetric pricing rule within sellers in equilibrium.²¹ Hence, the demand function in equation (E.2) can be expressed as:

$$R_{sd} = \phi_{sd} r_{sd}^{-\sigma} b_{sd}^{\frac{\rho-\sigma}{1-\rho}} r_d^{\sigma-1} \beta \bar{t}_d p_d Y_d. \quad (\text{E.5})$$

²¹This equilibrium condition parallels the one derived by [Hottman et al. \(2016\)](#) for multi-product firms.

The sellers' maximization problem can be formulated as:

$$\max_{\{r_{sd}, b_{sd}\} \geq 0} (r_{sd} - w_d(n))b_{sd}R_{sd} - w_d(n)\frac{b_{sd}^{1+\frac{1}{\lambda}}}{1+\frac{1}{\lambda}} - w_d(n)f, \quad \lambda > 0 \quad (\text{E.6})$$

$$\text{s.t. equation (E.5).} \quad (\text{E.7})$$

The first-order conditions associated with this problem deliver the following equilibrium expressions for the price of robots and number of branches:

$$r_{sd} = \frac{\varepsilon_{sd}}{\varepsilon_{sd} - 1}w_d(n), \quad b_{sd} = \left[\frac{(r_{sd} - w_d(n))(\sigma - 1)(1 - s_{sd})\tilde{R}_{sd}\phi_{sd}}{(\rho - 1)w_d(n)} \right]^\lambda. \quad (\text{E.8})$$

\tilde{R}_{sd} is quality-adjusted robot demand. The market share of seller s in market d is:

$$s_{sd} = \frac{\phi_{sd}b_{sd}^{\frac{1-\rho}{1-\sigma}}r_{sd}^{1-\sigma}}{\sum_{s \in S_d} \phi_{sd}b_{sd}^{\frac{1-\rho}{1-\sigma}}r_{sd}^{1-\sigma}}. \quad (\text{E.9})$$

All else equal, sellers with higher ϕ_{sd} open more branches, sell more robots, and charge higher markups.

Closing the Model. The other equilibrium conditions are unchanged, except for the non-routine labor market clearing condition which now reads:

$$\bar{L}_d(n) = \frac{(1 - \beta)p_d Y_d}{w_d(n)} + R_d + \sum_{s \in S_d} \frac{b_{sd}^{1+\frac{1}{\lambda}}}{1+\frac{1}{\lambda}} + |S_d|f. \quad (\text{E.10})$$

E.2 Alternative Marginal Cost Specifications

The baseline model assumes that robot sellers only need local non-routine workers to sell products (i.e., indivisible bundles of generic robots and integration services). I impose this assumption to abstract from the production and exports of generic robots and focus on competition in sales in destination markets. In this section, I discuss how to allow for production and trade in generic robots.

Accounting for Production and Trade in Generic Robots. Generic robots are produced by MNEs in their HQ market o , exported to a destination market d , and

sold there bundled with integration services. MNEs need non-routine labor to produce generic robots in o .²² As in the baseline model, selling generic robots bundled with integration services in d requires local non-routine labor. In this case, the marginal cost of selling robots in market d is:

$$t_{od}w_o(n)^\gamma w_d(n)^{1-\gamma}, \quad \gamma \in (0, 1). \quad (\text{E.11})$$

Let $t_{od} = 1$ if $o = d$ and $t_{od} \geq 1$ if $o \neq d$. This term captures the trade cost that MNE s from market o faces when selling robots in a foreign market d . This specification implies that entry in the robot sector of market d is constrained both by the available amount of non-routine workers in d as well as in the HQ country, and equation (21) should be modified accordingly. If robot production requires paying a fixed cost in terms of non-routine labor in the HQ country, this cost must be subtracted from MNEs' profits in equation (8).

E.3 Derivations

This section shows the derivations generating Figure 3.

Entry Reduces Incumbents' Prices. The price of any symmetric incumbent robot seller is, for $w(n) = 1$:

$$r = \mu = \frac{\sigma - (\sigma - 1)\frac{1}{|S|}}{\sigma - (\sigma - 1)\frac{1}{|S|} - 1}. \quad (\text{E.12})$$

Therefore:

$$\frac{\partial r}{\partial |S|} \frac{|S|}{r} = \frac{\partial \log r}{\partial |S|} |S| = \left(\frac{(\sigma - 1)(\varepsilon - 1)\frac{1}{|S|^2} - (\sigma - 1)\varepsilon\frac{1}{|S|^2}}{\mu(\varepsilon - 1)^2} \right) |S| \quad (\text{E.13})$$

$$= \frac{(1 - \sigma)}{\varepsilon(\varepsilon - 1)^2 |S|} < 0. \quad (\text{E.14})$$

²²This assumption can be relaxed to allow robot production require both routine and non-routine workers in the HQ.

Entry Reduces the Aggregate Robot Price. The log of the aggregate price of robots is:

$$\log \check{r} = \frac{1}{1-\sigma} \log |S| + \log r + \frac{1}{1-\sigma} \log \phi. \quad (\text{E.15})$$

Therefore:

$$\frac{\partial \check{r}}{\partial |S|} \frac{|S|}{\check{r}} = \frac{\partial \log \check{r}}{\partial |S|} |S| = \left(\frac{1}{(1-\sigma)|S|} + \frac{1}{r} \frac{\partial r}{\partial |S|} \right) |S| \quad (\text{E.16})$$

$$= \frac{1}{(1-\sigma)} + \frac{\partial r}{\partial |S|} \frac{|S|}{r} \quad (\text{E.17})$$

$$= \frac{1}{(1-\sigma)} + \frac{(1-\sigma)}{\varepsilon(\varepsilon-1)^2 |S|} < 0. \quad (\text{E.18})$$

Entry Reduces the Price Index. The log of the aggregate price index is:

$$\log p = \log \left(\frac{\bar{\beta}}{A} \right) + \beta \log \check{r} \quad (\text{E.19})$$

Therefore:

$$\frac{\partial p}{\partial |S|} \frac{|S|}{p} = \frac{\partial \log p}{\partial |S|} |S| = \beta \frac{\partial \check{r}}{\partial |S|} \frac{|S|}{\check{r}} = \frac{\beta}{(1-\sigma)} + \frac{\beta(1-\sigma)}{\varepsilon(\varepsilon-1)^2 |S|} < 0. \quad (\text{E.20})$$

F Quantitative Appendix

F.1 Algorithm to Solve the Model

Given the parameters in Table 2, the model can be solved using the following algorithm:

1. Guess a value of $w_d(n)$ and r_d for each market as well as aggregate profits Π ;
2. Set $r_d = w_d(r)$ and find $p_d = \bar{\beta} w_d(r)^\beta w_d(n)^{1-\beta} / A_d$, $\bar{\beta} = \beta^{-\beta} (1-\beta)^{\beta-1}$;
3. Find Y_d using equation (19) and $\bar{\tau}_d$ using equation (20). Then compute the expenditure on robots $\beta \bar{\tau}_d p_d Y_d$ in each market;
4. Solve the sellers' sequential entry game market-by-market:
 - (a) Let $S = 1$. Use a fixed-point search to find r_{sd} from equation (14);
 - (b) Compute profits π_{sd} ;

- (c) If $\pi_{sd} > w_d(n)f$, let $S = 2$ and repeat from (4.a);
 - (d) Stop when last entrant would make negative profits.
5. Find a new vector of market-level robot prices r'_d and aggregate profits Π' ;
 6. Find a new vector of market-level non-routine wages $w_d(n)'$ (up to a numéraire);
 7. Iterate until $\|r_d - r'_d\| < tol$, $\|w_d(n) - w_d(n)'\| < tol$, and $|\Pi - \Pi'| < tol$.

When searching for the fixed point of the robot sellers' problem and the GE allocation, I follow [Gaubert and Itskhoki \(2021\)](#) and update prices taking a half step between the old guess and the new one at each iteration. Notice that equation (14) is only defined for $S \geq 2$. When initializing the inner loop to solve the sellers' problem, I modify equation (14) assuming that the seller behaves as a local monopolist. In this case, the optimal pricing rule can be written as $r_{sd} = \frac{\sigma}{\sigma-1}w_d(n)$.

F.2 Simulated Method of Moments Algorithm

The SMM procedure to find the parameters to be estimated in Table 2 reads as follows:

1. Draw B matrices with dimension $|\mathcal{S}| \times |\mathcal{M}|$ of normally distributed i.i.d. shocks with mean zero and unit variance, being $|\mathcal{S}|$ the total number of sellers and $|\mathcal{M}|$ the total number of markets. I use Sobol sequences to cover the support of the normal distribution more efficiently than if numbers were drawn at random. In practice, I set $B = 200$;
2. Guess a vector of parameters Θ ;
3. For each of the B matrices of random shocks:
 - (a) Compute demand shifters using equation (26);
 - (b) Solve the model using the algorithm described in Section F.1;
 - (c) Compute the model-implied moments of interest and store them.
4. Compute the average model-implied moments of interest across the B samples. Denote $m(\Theta)$ the resulting vector;
5. Update the guess of Θ to minimize the SMM objective function $\mathcal{L}(\Theta) = (m(\Theta) - \bar{m})'W(m(\Theta) - \bar{m})$.

In operationalize this procedure in two steps. First, I adopt an adaptive radius limited differential evolution algorithm to find the starting values of the SMM routine.²³ Second, I run a local search using a standard quasi-Newton algorithm around these values. In practice, this second step stops after a few iterations and only marginally reduces the SMM objective function. The confidence intervals in Table 2 are computed using the bootstrap procedure of Bernard et al. (2022). The procedure is performed as follows. First, for each bootstrap sample, I draw sellers and markets with replacement until I obtain the same sample size as in the data. Second, I compute the empirical moments used in the SMM procedure for each bootstrap sample. Third, I estimate the model parameters at each sample using the procedure described above. The standard errors in Table 2 are the standard deviation of the distribution of the estimates across samples. I employ 200 replications.

F.3 Counterfactual Scenario: Robot Tax

Algorithm. I modify the algorithm in Section F.1 to account for the presence of a tax as follows:

1. Guess a value of $w_d(n)$ and r_d for each market as well as aggregate profits Π and total tax transfers $T_{EU} = \sum_{d \in \mathcal{M}} \mathbf{1}\{d \in EU\} t_d r_d R_d$;
2. Set $r_d = (1 + \tau_d) w_d(r)$ and find $p_d = \bar{\beta} w_d(r)^\beta w_d(n)^{1-\beta} / A_d$, $\bar{\beta} = \beta^{-\beta} (1 - \beta)^{\beta-1}$;
3. Find households' disposable income $E_d(i)$ using equation (4);
4. Find Y_d using equation (19) and \bar{t}_d using equation (20). Then compute the expenditure on robots $\beta \bar{t}_d p_d Y_d$ in each market;
5. Solve the sellers' sequential entry game market-by-market:
 - (a) Let $S = 1$. Use a fixed-point search to find r_{sd} from equation (14);
 - (b) Compute profits π_{sd} ;
 - (c) If $\pi_{sd} > w_d(n)f$, let $S = 2$ and repeat from (5.a);
 - (d) Stop when last entrant would make negative profits.

²³This algorithm is available through the Julia package `BlackBoxOptim.jl`, and it is shown to perform well in finding the global minimum of non-linear problems.

6. Find a new vector of market-level robot prices r'_d , aggregate profits Π' , and tax transfers T'_{EU} ;
7. Find a new vector of market-level non-routine wages $w_d(n)'$ (up to a numéraire);
8. Iterate until $\|r_d - r'_d\| < tol$, $\|w_d(n) - w_d(n)'\| < tol$, $|\Pi - \Pi'| < tol$ and $|T_{EU} - T'_{EU}| < tol$.

Also in this case, I update prices taking a half step between the old guess and the new one at each iteration. As before, I modify equation (14) assuming that the seller behaves as a local monopolist when $S_d = 1$.

First Scenario. In the first scenario, the counterfactual outcomes are computed as follows:

1. For each of the B matrices of ϕ_{sd} demand shifters used in the SMM procedure (see Section F.2):
 - (a) Solve the model without tax using the algorithm described in Section F.1;
 - (b) Store the number of sellers per market S_d and their demand shifters ϕ_{sd} ;
 - (c) Find the equilibrium of the model without and with tax given S_d and ϕ_{sd} . This can be done by using the algorithm described in the paragraph at the beginning of Section F.3 but skipping step 8;
 - (d) Compute the percentage changes in the outcomes of interest between equilibria.
2. Compute the average change in the outcomes of interest across the B draws.

Second Scenario. In the second scenario, the counterfactual outcomes are computed as follows:

1. For each of the B matrices of ϕ_{sd} demand shifters used in the SMM procedure (see Section F.2):
 - (a) Solve the model without tax using the algorithm described in Section F.1;
 - (b) Solve the model with tax using the algorithm described in the paragraph at the beginning of Section F.3;

(c) Compute the percentage changes in the outcomes of interest between equilibria.

2. Compute the average change in the outcomes of interest across the B draws.

I assume that a robot tax is implemented before robot sellers make entry choices. In the first scenario, this choice is inconsequential because entry choices and markups are held constant. In the second, it requires solving the problem of robot sellers in an economy without and with taxes (i.e., one in which $\tau_d = 0$ everywhere and one in which $\tau_{EU} = 5\%$).

F.4 Counterfactual Scenario: Competition Policy

I use the algorithm in Section F.1 to solve for the new equilibrium. When reducing entry costs while keeping the number of robot sellers constant, I simply discount the parameter f before solving the model. To simulate the entry of a new Asian robot seller, I add a row to the matrix of demand shifters in equation (26). I assign to this new robot seller ϕ_H as average appeal. The distance from China to each country comes from the data. Error terms are sampled from the $N(0, 1)$ distribution.
